ABSTRACT

Although there are many existing models on leadership, they have two problems. First, prevailing models focus more on the competencies (i.e., “doing”) instead of personal qualities (i.e., “being”) of leaders. Second, most of the models are developed with reference to adults in the business settings instead of young people who are not working. Drawing on the literature on positive youth development and the experiences gained from The Hong Kong Polytechnic University, it is argued that a holistic youth leadership framework should focus on several attributes, including: a) social responsibility (passion about the needy and motivation to serve); b) excellence (excel in different areas, particularly in the domains of intrapersonal and interpersonal development); c) reflection (ability to honestly assess one's strengths, weaknesses and behavior); d) visionary (youth leaders should have visions particularly with reference to

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

the needs and problems of the society and the world); and e) ethical leadership (moral character is the foundation of leaders). Using the first letter in these attributes, a “SERVE” model is proposed to guide youth leadership programs.

INTRODUCTION

Leadership is an important dimension in organizations. Without a good leader, organizations do not thrive and the directions of development are blurred. Hence, leadership development forms an important dimension in organizational behavior, particularly in the business field. Conceptually speaking, many leadership models focusing on the competencies of leaders (particularly management skills) have been proposed. In the management field, most of the leadership skills focus on management skills and efficiency enhancement. Practically speaking, many leadership programs have been developed by many management consulting companies which pledge to nurture leaders who will promote efficiency and profit maximization in organizations. For some famous programs, the fee is enormously high.

Unfortunately, there are two basic problems of the existing models on leadership, particularly those evolved from the business sector. First, most of the existing leadership models are developed for adults [1]. As the developmental tasks of adults are different from those of adolescents, there is a need to develop leadership models with particular reference to the developmental needs and challenges of young people. Second, youth leadership programs commonly lack developmental focus [2], focusing too much on competence but not values [3]. Besides, evaluation studies on youth leadership programs are severely lacking in the field [4]. Against this background, there is a need to highlight the desired leadership qualities in young people which will guide leadership programs.

The positive youth development approach forms an important anchor for the development of youth leadership program. According to the positive youth development approach, there are strengths and talents in every young person [5]. Hence, it is maintained that every young person can be (and is) a leader [6]. This view is in sharp contrast to the notion of “elitist leadership” which upholds that only the “cream of the cream” can be leaders. Consistent with such views, there are views asserting that leadership knowledge, attitude, values, and behavior can be trained through well-designed leadership programs [7]. In other words, given appropriate opportunities, young people can develop leadership qualities. This view is in sharp contrast to the view that leaders are inborn and there is little room for the nurturance of leadership development. Furthermore, developmental psychologists and youth workers also argue that we should expect young people to strive for excellence in different domains (i.e., aiming high and trying to excel) so that they can have self-actualization [8].

There are several points we have to consider when we design leadership models for young people. First, many theorists suggest that training of management skills is fundamental to leadership training programs [7]. However, there are also views arguing that while leadership skills (i.e., “doing”) such as resilience (adversity quotient, AQ) and emotional competence (emotional quotient, EQ) are necessary for leadership effectiveness, development of intrapersonal qualities (i.e., “being”), such as spirituality (spiritual quotient, SQ) and moral character are equally important [9-11]. Besides, there are also views maintaining that reflection and self-leadership [12] are important attributes of successful leadership.

Regarding intrapersonal qualities, two attributes deserve particular attention. The first is reflection. Reflection basically means stepping back and pondering about the reality. For a mature leader, he/she will think about whether his/her leadership is desirable or not and how the related leadership can be improved. Another attribute that is very important for successful leadership is ethical leadership. A mature leader cherishes moral values such as fairness, justice, and concern about other people. It can be argued that without ethics, a leader with excellent skills would do more harms than good. For example, a very skillful leader may have excellent strategies to earn money from the customers by producing harmful products.

A successful leader never lives in a vacuum. Besides nurturing one's inner qualities, a successful leader leads the followers. Hence, a leader should have good interpersonal relationship qualities, such as relationship building, collaboration, team building, conflict resolution and building consensus. Most important of all, successful leaders should gain respect and trust from the followers and co-workers [13]. With reference to the growing egocentrism and drop of empathy in young people, interpersonal competence is very important for young leaders.

Besides leadership skills, young leaders have to re-think about one's relationship with the society. As young people are pillars of the society in future, young people are also expected to have visions about the community, society, nation and the world they live in. In particular, young leaders should be sensitive to the needs of the society and go beyond self-serving interests to serve and contribute to the needs of others [14].

Finally, as leadership programs are human service programs, it is important to evaluate the effectiveness and impact of the programs [15]. As systematic evaluation studies on leadership are sparse, it is important to conduct systematic evaluation so that evidence-based leadership programs can be developed.

Based on the above discussion, several principles should be emphasized when we design leadership subjects or programs for young people. These include:

- Principle 1: In contrast to the notion of “elitist leadership,” we should believe that every student is (and can be) a leader.
- Principle 2: Leadership knowledge, attitude, values and behavior can be trained through well-designed leadership programs. That is, leadership qualities can be nurtured.
- Principle 3: Before one can lead others, one must lead oneself. In other words, self-leadership is important.
- Principle 4: Besides generic leadership competence such as management skills, intrapersonal and interpersonal development (i.e., “being”) of the leader determines the quality of leadership behavior (i.e., “doing”).
- Principle 5: Interpersonal relationship qualities are essential for a successful leader.
- Principle 6: Leaders should be sensitive to the needs of the society. Hence, leadership goes beyond self-serving interests to serve and contribute to the needs of the needy.
- Principle 7: Evidence-based leadership programs are necessary. Hence, evaluation plays a key role in the development of effective leadership programs.

LEADERSHIP DEVELOPMENT AT THE HONG KONG POLYTECHNIC UNIVERSITY

The above core beliefs are translated into actual leadership courses and programs at The Hong Kong Polytechnic University (PolyU). Since the inception of the 4-year undergraduate program, both credit-bearing leadership subjects and non-credit-bearing leadership programs have been developed. With particular reference to the credit bearing subjects, three subjects deserve particular attention.

Leadership Subject 1 (Tomorrow's Leaders)

There are many developmental issues in university students, such as mental health issues and rising in egocentrism. Although universities should promote holistic development in students, there are criticisms that universities have failed to perform this duty [16]. As pointed out by Harry Lewis [17], "over the decades I have heard many academic discussions about teaching, about the curriculum, about grading, about athletics, and about responding to student misdeeds. I have almost never heard discussions among professors about making students better people" (p. xv). Dalton and Crosby [18] similarly argued that university education fails to help students to "make internal connections to the defining beliefs and purposes in their lives ... since they do not reach that part of students' lives where things really matter" (p. 1).

Against the above background, we have developed a subject entitled "Tomorrow's Leaders" at The Hong Kong Polytechnic University based on the positive youth development (PYD) approach. According to the PYD approach, psychosocial competencies are vital to student development. The PYD approach is widely adopted in youth enhancement programs. In this subject, there is an integration of theories and research on PYD and leadership. Through curricula-based program and experiential learning activities, students learn and reflect on their intrapersonal and leadership competencies.

The subject is truly innovative and integrative in terms of curriculum design. Several features are intrinsic to the curriculum design: a) emphasis on both academic knowledge and personal development; b) expectation of high level of teacher-student and student-student interactions; c) learning from experience (experiential learning); d) learning through reflection (reflective learning); e) learning in group (collaborative learning); f) creation of enjoyable learning experiences for the students; g) high expectations of student participation and responsive teaching style; and h) use of peer assessment for class participation. There are several core beliefs in this subject as follows:

- 1) Every student is (and can be) a leader, although most students may not be aware of their potential and abilities.
- 2) Self-understanding and intrapersonal competence are very important to effective leadership. Through the structured and systematic curriculum, self-understanding, interpersonal communication and ethical leadership in students will be enhanced.

- 3) Experiential learning is an important vehicle to help students understand themselves. As such, individual, group, and class experiential learning activities with high interaction among the students are developed.
- 4) Individual reflection is the key to student development and learning.
- 5) Collaborative learning can help students develop intrapersonal and interpersonal competence. Learning through group sharing, discussion, evaluation and presentation is important.
- 6) There is an equal emphasis on the academic knowledge of positive youth development and leadership as well as on the application of knowledge in real life. Students are encouraged to consciously apply what they have learned to their lives.
- 7) Systematic evaluation utilizing different evaluation mechanisms is crucial to understanding the effectiveness of the subject developed.

Before the subject was formally implemented in 2012/13 school year, it was piloted in 2010/11 and 2011/12 school years, with 463 students taking the subject. From 2012/13 school year onwards, the subject was offered to more than 2,000 students per year. To date, the subject has been taken by almost 10,000 students. Multiple evaluation strategies were adopted to understand the impact of the subject:

- 1) Objective outcome evaluation: One group pretest-posttest design was used to assess the impact of the subject using a validated instrument. For the pilot subjects, results revealed that there was a significant increase in scores in different domains, such as emotional competence and social competence. For the subjects implemented in the full implementation phase, there were also findings suggesting that students changed in the positive direction in different measures.
- 2) Subjective outcome evaluation: Subjective outcome evaluation data were collected after each lecture and after completion of the subject using validated instruments. In the pilot and full implementation stages, findings showed that students had a positive perception of the subject and instructors, and they perceived that the subject was beneficial to their development.
- 3) Process evaluation: Process evaluation was conducted using a validated instrument assessing the program implementation quality and program adherence. The findings suggest that program adherence as well as quality of program implementation were high.
- 4) Qualitative evaluation: Qualitative evaluation was conducted through written reflective journals from students and focus groups. In the pilot and full implementation stages, findings showed that there were positive perceptions of the students regarding the subject, instructors, and benefits of the subject.

In addition, the multiple studies on the effectiveness of General University Requirements (GUR) curricula – general education that aims at promoting holistic development of students, also suggested that this subject was successfully implemented and well-received by the students (see the list of publications in Appendix 1). This subject was shortlisted for the QS STARS 2015 Reimagine Education Awards which had more than 500 entries in the competition.

Leadership Subject 2 (Service Leadership)

With the industrial transformation and globalization, Hong Kong has shifted its economic structure from manufacturing to service-oriented economy with approximately 95% of GDP coming from service industries. The success of service economy demands a paradigm shift in leadership, particularly from an industrial orientation focusing on control, efficiency, and financial interest to a postindustrial orientation emphasizing relationship between the service provider and service recipient, integrity, and care [19]. Hence, universities should take the responsibility to nurture their students to be effective leaders who meet such demands. However, higher education in Hong Kong fails to develop leaders in a holistic manner [20]. Leadership qualities such as care and moral character are often overlooked.

Against the above background, we have developed a credit-bearing subject entitled “Service Leadership” at The Hong Kong Polytechnic University based on the Service Leadership and Management (SLAM) curriculum framework proposed by Dr. Po Chung, the Co-founder of DHL International (Asia Pacific). Chung [21] defined service leadership as “satisfying needs by consistently providing quality personal service to everyone one comes into contact with, including one’s self, others, groups, communities, systems, and environments.” SLAM proposes that the effectiveness of leadership (E) is a function of three fundamental factors, including competencies (C) of the leaders, caring disposition (C) and moral character (M) of the leaders perceived by superiors, subordinates and peers, which can be summarized as $E=MC^2$. Therefore, in addition to competencies, strong emphasis is placed on cultivating students’ caring disposition and moral character in this subject.

Therefore, we offered a 3-credit subject entitled “Service Leadership” at The Hong Kong Polytechnic University. This subject is open to all the university students with an overarching goal to nurture effective service leaders. First, this subject intends to bring a paradigm shift in the students’ mindset about leadership and cultivate their understanding of the basic qualities of service leaders. Next, this subject aims to help students reflect on and develop their competencies (including intrapersonal competencies and interpersonal competencies), caring disposition (listening, empathy and love) and moral character (character strengths and Chinese virtues). Finally, this subject intends to help students understand the importance of service leadership to the quality of life of individuals, other people, and the society.

The Service Leadership and Management (SLAM) framework proposes that effective service leadership is not only determined by how competent the leader is, but also by how much the leader possesses moral character and a caring disposition. Therefore, the subject includes topics on the basic service leadership theory (i.e., seven core beliefs and three realms of service leadership) and three essential leadership qualities (i.e., competencies, caring disposition and moral character). The teaching/learning methodology includes lectures, experiential classroom activities, reflective exercises, a group project presentation and an individual paper. Our teaching philosophy for this subject is outlined below:

- 1) Every student is (and can be) a leader. Teachers should encourage every student to develop his/her leadership and appreciate the merits of every student.
- 2) Self-understanding and self-reflection are very important for effective service leadership. Individual self-reflection exercises should be conducted, which allows students to enhance their self-understanding.

- 3) Experiential learning is an effective approach to enhance student learning. Individual, group and class experiential learning activities should be conducted, in which students can work individually or collaboratively to experience the knowledge learned.
- 4) Collaborative learning can help students develop competencies, caring disposition and moral character. Learning will be facilitated through group sharing, discussion, evaluation and presentation.
- 5) Critical thinking is encouraged throughout the learning process. As such, debates and critical appraisal on the SLAM framework can be conducted, which allows students to think from multiple perspectives.
- 6) Equal emphasis is placed on the theoretical knowledge of service leadership and on the application of that knowledge in real life. Teachers should highlight the link between theoretical knowledge and students' lives and future careers. Students are encouraged to consciously apply the knowledge to their lives.
- 7) Systematic evaluation utilizing different evaluation approaches is critical to understanding the effectiveness of the course developed.

This subject was offered in 2012/13 academic year as a 2-credit General Education subject to students under the 3-year undergraduate program. A total of 190 students took this subject. In 2014/15 academic year, this subject was modified and enriched to be a 3-credit subject for students under the 4-year undergraduate program. A total of 207 students took this subject. Multiple evaluation approaches have been carried out to understand the effectiveness of the subject:

- 1) Objective outcome evaluation: One group pretest-posttest design was used to assess the outcome of the subject using a validated instrument. The results of all classes revealed that students in the 3-year program and 4-year program showed positive changes in measures of positive youth development, service leadership qualities and beliefs, and life satisfaction.
- 2) Subjective outcome evaluation: Subjective outcome evaluation data were collected after completion of the course using a validated instrument. The findings showed positive client satisfaction findings in the domains of subject design and implementation, instructor(s), and the gains from this subject.
- 3) Process evaluation: Two raters were typically involved to observe and assess program implementation quality and program adherence. The findings showed that program adherence and the implementation quality were high.
- 4) Qualitative evaluation: Qualitative evaluation was conducted through written reflective sheets and focus groups. The findings showed that students generally had positive perceptions of the subject, instructor(s), and the gains from this subject.

To date, the evaluation results have been published in refereed journals and in a book series entitled "Quality of Life in Asia" and two special issues in "International Journal on Disability and Human Development." The achievement of Service Leadership project will be also documented in a forthcoming special issue in "International Journal of Adolescent Medicine and Health" edited by Shek, Chung, Lin and Merrick. The publication list is

outlined in Appendix 2. This subject was awarded the Bronze Award under the “Ethical Leadership” category in the QS STARS 2016 Reimagine Education Awards.

Leadership Subject 3 (Service Leadership through Serving Children and Families with Special Needs)

In view of the need to promote service leadership for the post-industrial societies, a 3-credit Service-Learning course entitled “Service Leadership through Serving Children and Families with Special Needs” has been implementing in The Hong Kong Polytechnic University (PolyU) since the 2013/14 academic year. The course is a 2-semester course, which aims to develop service leadership of students through delivering high-quality services based on the framework of Service-Learning pedagogy. Service-Learning is an experiential learning pedagogy that aims to deepen students’ learning experiences through integrating community service with academic study and reflection. The authentic scenarios provide challenging and conflict-filled situations for students to handle. In Service-Learning, students are envisaged not only to provide service but also to foster their learning in the process. Besides, Service-Learning benefits both the students and the service recipients. Through engaging in serving the service targets, students are expected to promote their psychosocial development, cognitive development, and civic engagement.

The curriculum of this course was based on the Service Leadership and Management Model (SLAM) [21]. Seven core beliefs are intrinsic to the frame of reference in service leadership education, which was included in the subject as the overarching framework of the curriculum. Within the framework, the importance of generic leadership competencies, moral character and caring disposition are addressed. Besides intrapersonal competencies, interpersonal competencies are also addressed in the course. According to the course outline, this course is designed “to enable students to:

- a) understand the core attributes of a service leader;
- b) apply the core components of service leadership through the engagement of community-based service activities;
- c) develop self-awareness of sharing and empathy to others and the community; and
- d) reflect on their service leadership qualities, particularly intrapersonal and interpersonal competencies.”

The pedagogy used is based on Kolb’s [22] four-stage learning cycle, which emphasizes the importance of experiential learning. To benefit the most from the experience, the students systematically went through the four stages of the experiential learning cycle: concrete experience (“do” or “act” stage), reflective observation (“reflection” stage), abstract conceptualization (“thinking” stage), and active experimentation (“application” stage).

Students first attended lectures to acquire the basic understanding of the definitions, theories, and concepts about service leadership. Workshops were subsequently provided for students to develop their service proposals. Students applied knowledge that they learned on Service Leadership through activities in several service sites, including special schools, social welfare service units for preschool children with developmental problems, a drug

rehabilitation agency, and schools admitting students with social and economic deprivation. For example, we served students in Project WeCan which provides support for schools admitting students with academic and family needs.

To academically engage our students, the teaching and learning activities on this subject were designed to include 1) 10-hour e-learning to acquire knowledge about the concepts of Service-Learning; 2) lectures on service leadership; 3) small group discussions to prepare for the service project; 4) service provided to service targets. In terms of assessment for learning, reflective journal writings were given to allow students to deepen their learning experience. Feedback was provided by teachers to improve students' learning. In terms of assessment of learning, group presentations were done by individual groups to consolidate the learning experience of the groups as a whole by the end of the subject.

When the course was first launched in the 2013-14 academic year, there were 145 students enrolled in this course, which aimed at providing quality services in two non-government organizations, namely Society of Boys' Centres and Heep Hong Society. Up to the academic year of 2015/16, 476 students have enrolled in this course. Moreover, the number of service sites has also expanded to Christian Zheng Sheng College and over 10 participating schools/centers from Project WeCan, which located in different parts of Hong Kong. The increased number of the service sites denotes the increased impact of our project and demand from the participating schools and organizations. Moreover, the services delivered were not only beneficial to the service targets but also fostered the development of well-being of the PolyU students.

First, the agencies were highly satisfied with the students in terms of their positive service attitudes, caring disposition, service leadership towards service targets, problem-solving skills and reflective attitude in delivering services. Second, the PolyU students provided highly positive responses about the course. In a quantitative evaluation, over 90% of the respondents rated positively on the professional quality of teaching staff, effectiveness to promote service leadership, and holistic personal development. Students were also praised for their generic competences such as emotional competence, critical thinking, social competence and sense of responsibility.

Qualitatively speaking, students shared their learning gains through writing reflective journals in terms of leadership competences, moral competence, demonstrating care and empathy, active listening, roles and responsibilities during services, and the usefulness of the subject to prepare for their future. In addition to writing reflective journals, students who served in Christian Zheng Sheng College reflected that their service experience during the reflection time in service camp at nights. The students were also asked to write three descriptions and one metaphor to reflect their service learning experiences of the day. The students experienced the service as enjoyable and meaningful. One student even thought that the service changed his worldview. Overall speaking, the findings support the integration effects of service leadership and service learning to foster the development of well-being of PolyU students and the benefits towards the schools/NGOs in the community. This subject was awarded the Bronze Award under the "Ethical Leadership" category in the QS STARS 2016 Reimagine Education Awards.

Besides credit-bearing subjects, Service Leadership education is embedded in non-credit-bearing programs, including Wofoo Leaders' Network and leadership programs organized by the Global Youth Leadership Institute. For example, an intensive 3.5-day to 4-day programs on Service Leadership have been included in the related programs.

TOWARDS AN INTEGRATIVE AND HOLISTIC MODEL OF YOUTH LEADERSHIP DEVELOPMENT

Our experience in these credit-bearing subjects as well as non-credit-bearing subjects re-affirm the importance of the principles set out earlier in the paper. Based on our experience and a conceptual integration of the available models, there are several cardinal qualities to be nurtured in university students, which is represented by the acronym of SERVE – social responsibility, excellence, reflection, vision and ethical leadership. The conceptual model is presented in Table 1. This leadership model is consistent with the motto of PolyU of “to learn and to apply, for the benefit of mankind.” It is also in line with the vision of the Global Youth Leadership Institute “to nurture students to be leaders to be reflective and ethical leaders who are sensitive to the social needs in the local and global contexts.”

Table 1. Conceptual model on the leadership development model at PolyU

Leadership qualities	Expectation about the leaders	Definition
Social responsibility	Socially responsible	Having passion and compassion about other living beings; sensitive to the needs of the society; development of responsible citizenship
Excellence	Excel in different domains, particularly in intrapersonal and interpersonal development	Strive for excellence in different domains. In particular, striving for excellence in intrapersonal competence (such as AQ, EQ, and SQ) and interpersonal competence (such as respect for others and empathy)
Reflection	Reflective	Awareness of one’s leadership behavior particularly its impact on other people, self-evaluation, self-critical stand
Vision	Visionary	Having high expectations about oneself, others, society, and the world; actively developing ideas about ways to create a better world
Ethics	Ethical leadership	Development of moral character and virtues conducive to effective leadership

ACKNOWLEDGMENTS

This paper is based on a paper to be published in the *International Journal of Child and Adolescent Health*. The work is financially supported by the Global Youth Leadership Institute at The Hong Kong Polytechnic University.

ABSTRACT

The present chapter evaluated the implementation and impact of the “General University Requirements” (GUR) at The Hong Kong Polytechnic University (PolyU) using both quantitative and qualitative methods. Quantitative methods included a four-year longitudinal online survey, Collegiate Learning Assessment Plus (CLA+), and secondary analyses of student feedback data in different years. Qualitative methods included focus groups and qualitative evaluation forms involving students and teachers as well as a longitudinal case study. Results showed that students displayed positive development based on different developmental indicators of the five desired graduate attributes of PolyU in their study of the four-year program. Both students and teachers also generally showed positive perceptions of the GUR, with reference to its subject

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

content, teaching and learning, and benefits. Several major concerns regarding the GUR were also identified.

INTRODUCTION

In a fast-changing and increasingly uncertain society, general education has become more important. General education was defined by the Association of American Colleges and Universities (AAC&U) [1] as “that part of a liberal education curriculum that is shared by all students. It provides broad exposure to multiple disciplines and forms the basis for developing essential intellectual, civic, and practical capacities.” In the 21st century and an increasingly globalized age, company structure becomes flatter and company composition becomes more international; employees have more empowering, diverse and unstable work environment and professional life, which require them to be more flexible and diverse and to have strong social and cognitive skills such as communication, problem-solving, critical and integrative thinking, interpersonal relationship building, and cultural awareness [2, 3]. These social changes challenged higher education. General education is regarded as a crucial instrument to help students to form a foundation of knowledge and develop valuable skills such as communication, quantitative reasoning, and integrative and critical thinking to become lifelong learners and global citizens in a fast-changing and an interconnected world [4]. For example, in a report named *Higher education in developing countries: Peril and promise* published by the Task Force on Higher Education and Society (convened by the World Bank and UNESCO) in 2000 [5], it was stated that “a general education is an excellent form of preparation for the flexible knowledge-based careers that increasingly dominate the upper tiers of the modern labor force” [5, p. 83] and it can “promote responsible citizenship, ethical behavior, educational ambition, professional development in a broad range of fields, and even global integration” [5, p. 88].

Against the above backdrop, many countries have incorporated or are exploring different approaches of general education in their higher education curriculum to strengthen their students’ college learning experience. In this exploration, the models that were widely adopted or referred to were the models of general education in American higher education, in which students normally study a set of general education courses in their first and second college years and then gradually move to their specialized study in later years. Nowadays, the American mode of general education has been transplanted to the higher education systems in many countries and districts, including Japan, mainland China, Hong Kong, Taiwan, and other places [6, 7].

While the “American” models were widely adopted, there were different stages in their development. In the early days, the general education curriculum inherited the tradition of liberal education in some traditional famous English universities such as University of Oxford and University of Cambridge, which was manifested by a unified curriculum focusing on classical studies to develop lawyers, doctors and ministers for the upper class of a preindustrial society [8]. Since the late nineteenth century, the curriculum was challenged by the rapid industrialization and science development of American society and was replaced by a free elective system firstly proposed by Charles Eliot, the prior president of Harvard University, which offered students full freedom to choose subjects that fulfilled their individualized learning needs and interests [9, 10]. The free elective system was then replaced

by a “distributional requirement” due to the criticism that it lacked unification and integration in students’ learning [11]. The distributional requirement required students to take courses from each of a broad scope of disciplines with certain freedom which could balance the common requirements and students’ personalized interests [8]. In recent decades, some new curricular or course models were developed to meet with challenges of current social changes, including Freshman Experience program, interdisciplinary subjects, and service learning activities [8]. In a survey conducted by AAC&U in 2009 [1], 58% of AAC&U member institutions had developed First Year Experience programs in their general education curriculum preparing for their students’ first-year transition. Also, 39% institutions developed service learning programs in their general education curriculum and the percentage was still increasing. These developments showed the longstanding nature of general education and the new curricular models developed in it in coping with constant social changes.

Nevertheless, the implementation of general education is always a hard task and obstacles are bound to happen. Hence, constant evaluation and revision work need to be done to maintain healthy functioning and facilitate further improvement of general education programs and initiatives. In a report released by the Carnegie Foundation for the Advancement of Teaching in 1977 [12], general education in American universities was depicted as “a disaster area” and was blamed for its incoherence in programs. Challenged by these evaluation results, many universities and colleges reviewed and strengthened their general education programs in the 1980s [13]. Subsequently, from the 1990s to 2000s, the priority of general education has increased, more reforms were conducted and new models such as thematic programs were developed [14]. Also, more higher education institutions conducted formal review and assessment of their general education programs and even incorporated assessment as a routine practice in their program implementations [15].

With particular reference to Hong Kong, higher education in Hong Kong has experienced a comprehensive reform in the past few years, marking a shift from previous British-style to American-style undergraduate education. The previous undergraduate education in Hong Kong was based on a three-year curriculum, which highly emphasized early specialization and disciplinary concentration of students’ studies [16]. However, starting from the academic year of 2012-2013, all Hong Kong public universities extended their undergraduate curricula from three years to four years. At the same time, each university introduced a significant general education component in its new four-year undergraduate program which attempted to develop manpower with a broad knowledge scope, an innovative and integrated vision, positive attitudes and important generic and transferable skills to cope with the challenges of Hong Kong’s construction of a globally competitive and value-added service economy in the 21st century [16, 17] and development of a civil society as a Special Administrative Region of China [18].

However, there were very few evaluation studies to systematically evaluate these reform initiatives in Hong Kong universities. This research gap needs to be filled because evaluation can tell us how well the four-year undergraduate curricula and the new general education programs in different universities function, how effective they are, and what kind of promoting and hindering factors are existent in the functioning of these programs. Against this background, a comprehensive evaluation study was conducted to evaluate the new four-year curriculum and general education at The Hong Kong Polytechnic University (PolyU). In the 2012-2013 academic year, PolyU introduced a new general education structure into its new four-year curriculum framework. This general education structure is named “General

University Requirements” (GUR), which includes six major components. With this comprehensive structure, the GUR aims to develop PolyU students in five desired graduate attributes, including effective communication, critical thinking, innovative problem-solving, lifelong learning, and ethical leadership.

Freshman Seminar (FS)

FS is the first component of GUR. It is a three-credit mandatory subject offered by each faculty/school of PolyU to all its first-year students. FS aims to cultivate students’ understanding of their professions and broad disciplines and to develop their entrepreneurship and self-learning ability.

Leadership and Intrapersonal Development (LIPD)

LIPD component is intended to develop students’ understanding of intrapersonal and interpersonal skills that are needed for successful and ethical leaders. The component consists of two three-credit subjects. One is “Tomorrow’s Leaders” (TL) that is offered to all first-year students except for students of the Faculty of Business (FB), who are instead offered another subject named “Tango! Managing Self & Leading Others” (Tango!).

Language and Communication Requirements (LCR)

This component attempts to enhance students’ Chinese and English communication skills. The component requires students to take one Chinese and two English subjects according to their different language proficiencies.

Cluster Area Requirements (CAR)

This component requires students to take one three-credit subject in each of the four learning areas in addition to meeting three additional requirements, namely China studies requirements (CSR), English writing and reading requirements (EW/ER), and Chinese writing and reading requirements (CW/CR). The four learning areas are “Human Nature, Relations and Development” (CAR-A), “Community, Organization and Globalization” (CAR-B), “History, Culture and World Views” (CAR-C), and “Science, Technology, and Environment” (CAR-D). CAR aims to expand students’ intellectual potential and cultivate their understanding of the Chinese culture and their Chinese and English writing skills.

Service Learning (SL)

Each student needs to take a three-credit SL subject that includes a significant service component. This component aims to cultivate students' sense of social responsibility, empathy, and application of professional knowledge.

Healthy Lifestyle (HLS)

The HLS component is non-credit-bearing, whereby students are required to take a series of courses including introductory lecture, sports training, e-learning, and wrap-up lecture. The purpose of this component is to cultivate students' understanding of a healthy lifestyle and their mastery of related knowledge and skills.

To evaluate the implementation and effectiveness of the GUR, a five-year evaluation research was conducted. The research attempted to answer two basic evaluation questions: a) What are the changes in the students in their undergraduate study particularly with reference to the five desired graduate attributes of PolyU? b) What are the views of students and teachers on the GUR, especially in terms of content, teaching, implementation, and effects? To investigate these questions, different evaluation components were incorporated in the research, including:

- a) A four-year longitudinal online survey to track the development of students in a set of developmental indicators during their four-year study of the undergraduate curriculum and the GUR at PolyU
- b) Collegiate Learning Assessment Plus (CLA+) for assessing students' development in problem-solving, communication, and critical thinking in their study of the four-year curriculum
- c) Secondary data analyses of the Student Feedback Questionnaire (SFQ) data that was used to measure students' subjective outcome evaluation of GUR
- d) Student focus group interviews and qualitative evaluation based on evaluation forms used to understand students' perceptions of different subjects of GUR, especially the contents, teaching methods, implementation, and effects
- e) Teacher focus group interviews and qualitative evaluation based on evaluation forms, which was used to understand the teachers' view of the GUR curriculum, with reference to the curricular idea, teaching and learning, and curricular effects
- f) Longitudinal case study used to track the long-term development of students in the study of the four-year curriculum, and
- g) Repertory grid test to study the development of students after studying the four-year curriculum and the GUR.

A summary of different evaluation mechanisms and their major findings are presented in the sections below.

LONGITUDINAL ONLINE SURVEY

The longitudinal online survey attempted to investigate the changes of students under the new four-year undergraduate curriculum and the GUR at PolyU, with reference to the five desired graduate attributes (i.e., effective communication, critical thinking, innovative problem-solving, lifelong learning, and ethical leadership). This evaluation component included three sub-studies. Sub-Study 1 investigated the changes of PolyU four-year curriculum students in a set of developmental indicators in the four academic years from 2012-2013 to 2015-2016. Sub-Study 2 compared the performance of PolyU four-year curriculum students (Experimental Group) with those of PolyU three-year curriculum students (Control Group 1) in the 2014-2015 academic year (i.e., third-year students in the 3-year program and the 4-year program). Sub-Study 3 compared the performance of Experimental Group with those of four-year curriculum students in a comparable local university (Control Group 2) in the 2014-2015 academic year (i.e., third-year students in the 4-year program). Below is a summary of the three sub-studies.

Sub-Study 1

In the 2012-2013 academic year, 677 out of a random stratified sample of 1,000 first-year students enrolled in the new four-year curriculum of PolyU responded to an online questionnaire of GUR longitudinal online survey (Wave 1). These students were further invited to complete the same questionnaire annually in the following three academic years, i.e., 2013-2014 (Wave 2), 2014-2015 (Wave 3), and 2015-2016 (Wave 4) academic years. Of the 677 students initially invited, 434 had completed all four waves of the questionnaire.

The survey questionnaire was comprised of four validated instruments, including Chinese Interpersonal Reactivity Index (C-IRI), Chinese Positive Youth Development Scale (CPYDS), Index of Learning Style (ILS), and National Survey of Student Engagement (NSSE). The C-IRI comprises three subscales, including Personal Distress, Fantasy and Empathy, to measure empathy in Chinese people [19]. The CPYDS measures positive characteristics in Chinese adolescents [20]. A shortened version of CPYDS was adopted in the present longitudinal survey, which comprises 14 subscales including Cognitive Competence, Emotional Competence, Behavioral Competence, Problem Solving, Social Competence, Critical Thinking, Self-Determination, Self-Efficacy, Resilience, Moral Competence, Ethical Leadership, Self-Leadership, Life Satisfaction, and Lifelong Learning. The ILS measures students' individual learning preferences in terms of four dimensions: Active versus Reflective, Sensing versus Intuitive, Verbal versus Visual, and Global versus Sequential [21]. The NSSE measures students' engagement in learning and other university experiences, which consists of 11 subscales including Collaborative Learning, Reflective and Integrative Learning, Student Faculty Interaction, Higher Order Learning, Effective Teaching Practice, Quantitative Reasoning, Discuss with Diverse Other, Learning Strategies, High Impact Practice, Quality of Interaction, and Supportive Environment.

Repeated measures ANOVAs and Bonferroni post hoc tests were performed to compare the performance of the participants in indices of desired graduate attributes tested by survey instruments in the four academic years from 2012-2013 to 2015-2016. Results showed the

participants' increased ratings on the majority of indicators in their junior and senior years than in their freshman and sophomore years including problem-solving, collaborative learning, discuss with diverse other, higher order learning, reflective and integrative learning, and quantitative reasoning. Participants' ratings in the academic years of 2014-2015 and 2015-2016 were significantly higher than those in 2012-2013 and 2013-2014. The participants' ratings of critical thinking in the academic year of 2015-2016 were also higher than those in the academic years of 2012-2013 and 2013-2014. Their ratings of ethical leadership, self-leadership, and lifelong learning were also significantly higher in the academic year of 2015-2016 than in 2013-2014. Their ratings of learning strategies in 2015-2016 were higher than in 2013-2014, and their ratings in 2014-2015 were also higher than those in 2012-2013 and 2013-2014. The participants' ratings of social competence remained stable over the four academic years, and their empathy scores decreased in the academic year of 2013-2014 when compared to those in the year of 2012-2013. The findings for the changes in the students over time have been published [22].

Sub-Study 2 and Sub-Study 3

The sub-studies 2 and 3 were added to the whole study of the longitudinal survey in the 2014-2015 academic year (i.e., Year 3 of the cohort). While Sub-study 2 involved a control group consisting of 300 students enrolled in the old three-year undergraduate curriculum of PolyU (Control Group 1), Sub-study 3 involved a control group consisting of 300 students enrolled in a new four-year curriculum in a comparable local university (Control Group 2). Results of independent samples t-tests showed that the Experimental Group performed significantly better than Control Group 1 on critical thinking, ethical leadership, collaborative learning, discuss with diverse other, higher order learning, reflective and integrative learning, learning strategies and empathy, while the two groups had no differences in their performances on problem-solving, self-leadership, lifelong learning, and quantitative reasoning. The Experimental Group also performed significantly better than Control Group 2 on problem-solving, emotional competence, cognitive competence, behavioral competence, moral competence, life satisfaction, learning strategies, and quality of interaction. In short, the findings are consistent with the hypotheses of the study and they have been published elsewhere [23, 24].

COLLEGIATE LEARNING ASSESSMENT PLUS (CLA+)

The second quantitative method employed in the comprehensive evaluation research of the GUR was the Collegiate Learning Assessment Plus (CLA+). The CLA+ is a norm-referenced and standardized online test developed by the U.S. Council for Aid to Education (CAE). It assesses the contribution of an institution to the development of its students in competencies including analysis and problem-solving, writing effectiveness, writing mechanics, scientific and quantitative reasoning, critical reading and evaluation, and critique an argument [25]. These competencies are basically aligned with three desired graduate attributes of PolyU, namely, problem-solving, critical thinking, and effective communication.

Before the start and near the end of the 2013-2014 and 2015-2016 academic years, respectively, four rounds of CLA+ tests were performed with four groups of 150 randomly selected students who studied in the PolyU four-year curriculum. Group 1 consisted of 150 first-year students who conducted the test before the start of the 2013-2014 academic year. Group 2 was comprised of 150 second-year students participating in the test in Semester 2 of the 2013-2014 academic year. The 150 students were randomly selected from the participant pool of the longitudinal survey. Group 3 included 150 first-year students who completed the test before the start of the 2015-2016 academic year. Group 4 comprised 150 senior-year students participating in Semester 2 of the 2015-2016 academic year. Among the 150 participants in group 4, 127 were participants from Group 2.

Paired samples t-test comparing the performance of the 127 participants in both Group 2 and Group 4 showed that Group 4 scored significantly higher than Group 2 in almost all the variables of CLA+, including analyses and problem-solving, writing mechanics, scientific and quantitative reasoning, critical reading and evaluation, and critique an argument except for writing effectiveness on which the two groups had no differences in performance. Secondly, the independent samples t-test comparing the performance of Group 1 and Group 4 showed that Group 4 performed significantly better than Group 1 in all CLA+ subscales, except for writing mechanics on which the two groups performed comparable to each other. All the results indicated students' improvements in problem solving (measured by analyses & problem-solving), effective communication (measured by writing mechanics and writing Effectiveness) and critical thinking (assessed by scientific & quantitative reasoning, critical reading and evaluation, and critique an argument) in senior year than in freshmen and sophomore years under their study of the PolyU four-year curriculum and the GUR. A paper reporting the findings is under preparation [26].

SECONDARY DATA ANALYSES OF DATA FROM STUDENT FEEDBACK QUESTIONNAIRES (SFQ)

Secondary data analyses of the SFQ data were conducted to investigate students' subjective views of GUR subjects in terms of subject attributes and teacher attributes. In the academic years of 2012-2013, 2013-2014, 2014-2015 and 2015-2016, 16,909, 19,242, 24,902 and 24,360 SFQ on GUR subjects were collected, respectively, by the Educational Development Centre (EDC) of PolyU. The SFQ was a faculty/school-based questionnaire developed by EDC to assess perceptions of students on university subjects in each semester in terms of students' learning experiences and perceived teaching of staff. The present study gathered data from six standardized items in SFQ for GUR subjects for further analyses. The six items include four items concerning students' learning experiences in GUR subjects and two items on students' views of the teaching staff.

Results showed higher mean scores of students' ratings of all six SFQ items in all the four years. All the mean scores were above (or equal to) 4.00 out of a maximum of five, except for two ratings being 3.90. Results of the one-way ANOVA and post hoc comparison showed that students' ratings of almost all the items in the academic years of 2014-2015 and 2015-2016 were significantly higher than in academic years 2012-2013 and 2013-2014. The SFQ ratings for different GUR components were also positive. For LCR-English and LCR-

Chinese components, the mean scores of all items in all the four years were above (or equal to) 4.00, except for the score of one item in LCR-Chinese being 3.90. The mean scores for CAR, LIPD and SL were all above (or equal to) 3.70. Only the mean scores for FS were slightly lower, ranging from 3.40 to 4.10. Result based on one-way ANOVA and post hoc comparisons showed that on most of the SFQ items, students' ratings in FS, LCR, and CAR components had increased in the academic year of 2015-2016 compared to their ratings in 2012-2013. For LIPD, students' ratings of all items in the academic year of 2014-2015 were higher than those in 2013-2014, and their ratings of some items in 2014-2015 were also higher than those in 2012-2013. Students' SFQ ratings in SL component remained stable across the four academic years. These results indicated that students' evaluation of different GUR components were generally positive in the four years. These findings are published in different journals [27-29].

STUDENT FOCUS GROUPS AND QUALITATIVE EVALUATION BASED ON EVALUATION FORM

Student focus groups and qualitative evaluation based on evaluation form were conducted to understand students' subjective perceptions of the GUR subjects, especially their contents, teaching methods, implementation, and impacts. In each academic year, students were randomly selected from different faculties/schools to participate in focus group interviews. In the four academic years from 2012-2013 to 2015-2016, thirteen ($n = 62$), eighteen ($n = 74$), eight ($n = 73$), and eight ($n = 70$) student focus groups were conducted, respectively. In addition, in the academic years of 2013-2014 and 2014-2015, 320 and 480 randomly selected students studying in the four-year curriculum were invited to complete a qualitative evaluation form on their views of the GUR, respectively. A total of 163 evaluation forms from 2013-2014 and 332 from 2014-2015 academic years were collected from these students.

All focus groups were guided by a focus group protocol developed by the authors. The protocol consisted of several groups of questions to solicit the interviewees' views on rationales, teaching and learning, implementation and impacts of the GUR. The evaluation form was comprised of several open-ended questions to ask students to describe their general impressions of the GUR by using descriptors or short phrases, and to ask students about their unforgettable experiences, difficulties and personal achievements in their study of the GUR subjects. Thematic analyses were adopted to analyze the qualitative data collected.

The findings suggested that students' views of different GUR components were generally positive. The data collected from the qualitative evaluation form in different years indicated students' positive impressions and feelings of different GUR subjects. Different qualitative evaluation data also suggested that students perceived different GUR subjects positively with specific reference to content, teaching, implementation, and benefits. Students positively commented on the subject content of several components, such as LIPD, LCR-English, and CAR. Students perceived the topics in TL and CAR subjects as interesting and attractive and they perceived the contents of CAR and LCR-English subjects as practical and applicable to their lives and study. Students also liked the stratified teaching methods in LCR component and the design of CAR component that gave them freedom in selecting their interested subjects. Students had positive views of the active, interactive, and experiential teaching and

learning methods as well as the authentic assessment methods adopted in many GUR subjects. They perceived these methods as engaging, conducive to deep learning, and helpful to their achievement of the intended learning outcomes of different subjects. The findings are reported in a series of journal articles [30-33].

TEACHER FOCUS GROUPS AND QUALITATIVE EVALUATION BASED ON EVALUATION FORM

In each academic year from 2012-2013 to 2015-2016, a sample of teachers teaching different GUR subjects were invited to participate in focus group interviews based on nomination of program leaders and key teachers. In total, four ($n = 20$) focus groups in 2012-2013, eight ($n = 49$) in 2013-2014, eight ($n = 52$) in 2014-2015, and eight ($n = 50$) in 2015-2016 were conducted. Also, in the academic years of 2013-2014 and 2014-2015, 99 and 128 teachers teaching different GUR subjects were invited to complete a qualitative evaluation form, respectively. A total of 75 forms in 2013-2014 and 78 forms in 2014-2015 academic years were collected from the teachers.

All teacher focus groups were guided by a focus group protocol developed by the authors. The protocol included five groups of questions asking teachers to share their views on different aspects of the GUR subjects they taught, including rationale, impact on students, workable and unworkable subject components, and challenges to teaching. Teacher evaluation form included questions asking about teachers' general impression of the GUR subjects they taught, their perceived benefits of GUR, and the challenges in their teaching. Thematic analyses were used to analyze teacher focus group data and teacher evaluation form data.

Results showed that the teachers' views of the GUR were also generally positive. Teachers teaching different GUR subjects had positive impressions about the subjects they taught, which was evidenced by the high percentage of positive descriptors given by teachers in different GUR components in different academic years. Teachers in different GUR components positively perceived different aspects of the subjects they taught, including the general rationale, teaching methods, and impacts on students. Some teachers, particularly those teaching CAR subjects, displayed a deeper understanding of the rationale of the GUR and general education and gave highly positive support to GUR subjects. Many teachers perceived the active and interactive teaching and learning methods in their subjects as welcomed by students and engaged students in learning. The teachers also perceived a basic alignment of their subjects with the intended learning outcomes. Challenges were also noted, including teaching big classes in some GUR subjects and teaching FS subjects in some faculties composed by more diversified disciplines. The related findings are published in different papers [34-37].

LONGITUDINAL CASE STUDY

In the academic year of 2012-2013, 57 students participating in the student focus groups and additional 14 first-year students enrolled in the four-year curriculum of PolyU were

invited to participate in a four-year longitudinal case study to follow up the personal growth of these students under the study of the new curriculum and the GUR. In the academic year of 2013-2014, 42 active student cases were retained and the 29 inactive cases were removed from the study. The 42 cases were then followed up in the following three academic years from 2013-2014 to 2015-2016. At the end of each academic year, each student was invited to attend an individual interview to understand their personal growth and views of the four-year curriculum and the GUR in that year. The numbers of students who participated in interviews in each academic year were 71 in 2012-2013 (including the 14 newly recruited students participating in the individual interviews and the 57 focus group students), 31 in 2013-2014, 20 in 2014-2015, and 23 in 2015-2016. All the individual interviews were guided by an interview protocol developed by the research team. The data of 2014-2015 and 2015-2016 were still in analyses. The results of 2012-2013 and 2013-2014 have been published [38, 39].

REPERTORY GRID TEST

To assess the change in the undergraduate students with reference to the desired graduate attributes, a repertory grid test was adopted. In the second semester of the 2015-2016 academic year, a random stratified sample of 100 fourth-year students from the GUR longitudinal online survey cohort completed the repertory grid test. Basically, students perceived themselves as developing in a positive direction based on different indicators of self-identity. The findings provide support for the claim that GUR was able to promote positive development in undergraduate students over time. The analyses of data and paper writing are underway.

DISCUSSION AND CONCLUSION

This paper presented a five-year longitudinal and multi-method evaluation study on the implementation and impact of a new general education program entitled General University Requirements (GUR) in the new four-year undergraduate curriculum at The Hong Kong Polytechnic University (PolyU). Basically, whether students had changed in their study and how different stakeholders looked at the program were examined.

For the four-year longitudinal online survey (which also included a quasi-experimental design involving two control groups in one academic year, i.e., 2014-2015), the results indicated that the students had improved in almost all the five attributes. Besides, the CLA+ was used in the present study to assess students' changes in problem-solving, written communication, and critical thinking abilities after their study in the four-year curriculum and the GUR. The results also indicated students' significant improvements in these attributes.

These quantitative findings are further supported by the qualitative evaluation findings. In student and teacher focus groups, both students and teachers pointed out that the GUR structure facilitated students' holistic development. The qualitative data also suggested that good subject design, such as attractiveness and practicality of subject topics, and the design of teaching approaches to better deliver the topics and facilitate students' learning determined how well students could be benefited by the GUR subjects. This was in line with the literature

suggesting that a good subject design, such as those that could promote transferability and practicality of knowledge [40], together with active teaching and learning methods, such as collaborative learning and experiential learning, could increase student satisfaction with the general education subjects and could facilitate the goal-achievement of different general education programs [41, 42].

Regarding the question of how different stakeholders viewed the GUR, four methods were used, including Student Feedback Questionnaires (SFQ), student focus group and qualitative evaluation, teacher focus group and qualitative evaluation, and longitudinal case study. The SFQ results suggested that students had positive experiences of GUR subjects in terms of different aspects, and had positive evaluation of teaching staff. Particularly, for LCR component, students had highly positive evaluation and the evaluation had also increased over the four academic years. This observation was supported by the student and teacher focus group and qualitative evaluation findings. There are several explanations for this result. First, the LCR component was mainly designed to train students' English and Chinese writing and expression skills. In particular, the English LCR subjects trained students a lot on basic referencing and paper-writing skills and these skills could be directly applied by students in their study of other academic subjects involving essays-writing tasks. Secondly, with regard to LCR component (particularly the English LCR subjects), many subjects adopted a pedagogy that combined small-class teaching with a workshop style of instruction, which highly promoted student interaction with their teachers and enhanced student satisfaction with the subjects. The positive results of small-class and workshop style teaching were also supported by the existing literature [43, 44]. Thirdly, in English LCR, many subject teachers had overseas education experience and some were foreigners. These teachers' teaching styles might be more open, democratic and more welcomed by the students.

Besides, SFQ results suggested students' highly positive evaluation of teaching staff of LIPD component. There are two explanations for this. Firstly, since the LIPD component (particularly the TL subject) required teachers to show care, self-disclose, and provide assistance to their students, and stressed highly the teacher-student relationship, some teachers who could do this would receive high appreciation and recognition from their students. This was supported by the findings from student and teacher focus groups in the present study. Secondly, although the content of LIPD subjects, such as the content of TL subject, included many theories and concepts, excellent teachers who could better integrate these theories with appropriate teaching approaches and with their personal experiences could promote deeper learning in students and increase student satisfaction. This was supported by the previous studies on TL subjects [45, 46].

Nevertheless, this evaluation study highlighted some issues on the implementation of the GUR and in general education programs. One problem was teaching large class general education subjects. Nowadays, due to the restriction of university resources and classroom settings, large class teaching has become a trend. Therefore, how to implement effective teaching in big class, particularly how to better integrate traditional lecturing method and active teaching methods in large classes to promote students' learning has become a critical issue faced by many general education programs, including the GUR. Extant literature suggested that adding some active teaching methods such as in-class group discussion, short class presentation, poster sharing, and out of class reading tasks in traditional lecturing could effectively promote students' learning [47, 48]. Particularly, a study conducted by Morgan, Whorton and Gunsalus [49] even revealed that a combination of traditional lecture method

with group discussion resulted in better learning effects of students than totally using cooperative and active learning methods. These studies indicated a great potential to better design and utilize big class teaching to promote students' effective learning and provided directions for the further refinements of some GUR subjects.

Another problem was the challenge in teaching interdisciplinary subjects. This was manifested by both students' and teachers' concerns about FS subject implementation in the present study. One deeper reason for this was overspecialization of and strong boundary between knowledge disciplines in modern society, which made it increasingly harder for teachers in one discipline to understand the interconnections of their discipline with other disciplines. Without qualified teachers, the implementation of interdisciplinary subjects would be in vain. Studies suggested that more student-centered teaching and learning approaches, such as problem-based learning, enquiry-based learning, and learning communities, could help to facilitate student learning and engagement in interdisciplinary subjects [50, 51]. This was also supported by the findings of this study in that some FS subjects adopting more active learning approaches such as hands-on workshops led to much better learning among the students.

Two limitations of the present study should be noted. Firstly, some learning effects, particularly some long-term impacts or influence of the GUR, may not be identified in a short period. Therefore, it would be better to also investigate students' development and perceptions of the impact of GUR after their graduation. Secondly, although students and teachers are two important groups of stakeholders of the GUR, university administrators and policymakers were also important stakeholders of the GUR and their views should also be investigated. Despite of these limitations, the present study provides a comprehensive picture about the implementation and impact of the GUR at PolyU, which contributes to the existing literature on evaluation of general education.

ACKNOWLEDGMENTS

This work and the project entitled "The longitudinal evaluation of the General University Requirements under the new 4-year curriculum" are financially supported by the Learning and Teaching Committee at The Hong Kong Polytechnic University under Learning and Teaching Development Funding 2012-15. The authors declare that there is no conflict of interest with any financial organization regarding the material reported in this manuscript. ABSTRACT

In this chapter, we investigated how the new 4-year undergraduate program, particularly the “General University Requirements” (GUR) at The Hong Kong Polytechnic University (PolyU) contributed to the development of five desired graduate attributes amongst students of PolyU, including critical thinking, effective communication, innovative problem solving, lifelong learning and ethical leadership. The findings based on different evaluation methods, including longitudinal survey studies, Collegiate Learning Assessment Plus, secondary analyses of Student Feedback Questionnaire data, qualitative evaluation studies, longitudinal case study and repertory grid test evaluation are first summarized. Based on the findings, the question of whether the 4-year program contributed to the development of desired graduate attributes was explored. Integration of the available evaluation findings suggests that the GUR has

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

helped the undergraduate students to develop the graduate attributes and the new 4-year undergraduate programme can promote the holistic development of the students.

INTRODUCTION

Key generic competences such as effective communication, higher-order thinking, and problem-solving skills are becoming critically important in knowledge-based economy. There is no doubt that these competences were also stressed in previous times. However, in the previous era based on a manufacturing economy, the focus was mainly on the capital assets rather than the human assets [1]. Instead, in the current era dominated by a globalized knowledge economy and a service-based economy, the human assets play a key role in economic development [1]. Therefore, The Association of American Colleges and Universities issued a report named “*College learning for the new global century*” in 2007 [2]. The report proposed that the American university and college education should develop in students a set of core learning outcomes including knowledge of human cultures as well as physical and natural world, intellectual and practical skills, social responsibility, and integrative learning. Particularly, under the category of intellectual and practical skills, several key skills were stressed, including critical and creative thinking, written and oral communication, teamwork and problem solving. In addition, in order for developing these skills, the report called for a strengthening of general education programs in different American higher education institutions to foster “cross-disciplinary inquiry, analysis, and application” [2].

The review of goals of college education in the new century and its related curricular reforms have also been rigorously carried out in different places in Asia. In Mainland China, from the 1990s to the early 2000s, there had been a heated discussion on and rigorous implementation of quality education and general education in Chinese higher education institutions. Accompanying this was a deep reflection on what quality of manpower should be developed by Chinese higher education in the 21st century. Although various views emerged, their common threads were to develop high-quality graduates with strong flexibility, broad knowledge base, moral character and strong generic skills [3, 4]. Based on this consensus, many Chinese top universities have revised their Soviet-style overspecialized undergraduate curriculum by adding American elements of general education program [3, 5]. In Taiwan, the programs of general education had been introduced into higher education institutions since the 1950s and had undergone a rigorous and institutionalized development since the 1990s [6]. Up to the 2000s, almost all higher education institutions in Taiwan have implemented a formal general education program in their undergraduate curriculum [6]. Similarly, in Japan, general education programs had been introduced into Japanese higher education system since the 1950s and achieved a rigorous development in the 1960s. Although there was a decline in formal general education programs since the 1990s, the spirit of general education has been integrated into specialized education and achieved by various innovative pedagogy and curricula in different universities [7]. These different practices in different Asian areas illustrated that general education has become an important strategy for different areas to enhance their higher education quality and to develop more rounded manpower to rise up to the challenges of a more globalized society.

Besides actual practices in the undergraduate programs, theories of general education also suggested that it was a very important strategy to develop students' generic competences. Earlier in the 1820s, one famous report of Yale University [8, p.7] defended liberal education which is the predecessor of the current concept of general education, claiming that the core purpose of a liberal education was "discipline and furniture of the mind; expanding its powers, and storing it with knowledge." The Harvard report on general education entitled "*General education in a free society*" published in 1945 [9] also maintained that the essential aim of general education was to train students in four traits of mind, including "to think effectively, to communicate thought, to make relevant judgments, to discriminate among values." In addition, the previous President of Chicago University, Robert Maynard Hutchins, a famous advocator of general education and the founder of the classic books model of general education program in Chicago University in the 1930s and the 1940s, also stressed that the goal of general education was to "draw out the elements of our common human nature" [10]. These elements of common human nature were manifested in important intellectual virtues, such as the five intellectual virtues stressed in ancient times including the habits of induction, demonstration, philosophical wisdom, art, and prudence. These theoretical arguments and propositions further support the view that general education is an important curricular mean for students' development in important generic competences.

Among general education initiatives in Asian societies, Hong Kong can be regarded as a "late starter." Under the old British rule, there was not much room for the development of general education. Since the 2012-2013 academic year, mandated by the University Grants Committee, the higher education in Hong Kong has implemented a comprehensive reform on its undergraduate education program. Specifically, all the eight public universities in Hong Kong extended the length of their undergraduate degree programs from three years to four years. In addition, they introduced a significant general education structure in their new four-year undergraduate curricula. The reform was targeted to nurture a more flexible and rounded manpower to cope with challenges of Hong Kong's transformation from a manufacture-based to a service-based economy and its increasing integration into a globalized knowledge economy [11, 12].

Among all these reforms, the one at The Hong Kong Polytechnic University (PolyU) was unique. In the 2012-2013 academic year, PolyU transformed its undergraduate curriculum from three to four years in length. In the new four-year curriculum, a new general education framework entitled "General University Requirements" (GUR) was introduced. A major objective of the GUR was to nurture PolyU students in five desired graduate attributes, including effective communication, critical thinking, innovative problem solving, lifelong learning, and ethical leadership. These five attributes are regarded as key to PolyU students for their development to be locally and internationally competitive professionals and citizens.

The GUR is comprised of six major components, including freshman seminar (FS), leadership and intrapersonal development (LIPD), language and communication requirements (LCR), cluster area requirements (CAR), service learning (SL) and healthy lifestyle (HLS). Detailed introduction of these components can be seen in reference [13]. An alignment of different components with the five desired graduate attributes of PolyU is shown in Table 1.

Table 1. Alignment of GUR components with five desired graduate attributes of PolyU

	Professional competence	Critical thinker	Effective communicator	Innovative problem solver	Lifelong learner	Ethical leader
Freshman Seminar	○	○	○	○	○	
Language and Communication Requirements			●		○	
Leadership and Intrapersonal Development		○	○	○	●	●
Service Learning	○	●	○	●	○	●
Cluster Area Requirement		●	●		●	
Healthy Lifestyle Requirement					●	○

Note: ●: Target to make a significant contribution to the attribute; ○: Only some of the subjects/activities target to make a significant contribution to the attribute.

To gauge the effectiveness of the 4-year program and to understand the changes in the students, a longitudinal study was carried out from the academic years of 2012-2013 to 2015-2016. Seven evaluation components based on different methods were included in the project, including (a) a four-year longitudinal online survey, (b) Collegiate Learning Assessment Plus (CLA⁺), (c) secondary data analyses of the Student Feedback Questionnaire (SFQ) data for GUR subjects, (d) student focus groups and written qualitative evaluation, (e) teacher focus groups and written qualitative evaluation, (f) longitudinal case study, and (g) repertory grid test. This evaluation project has several distinctive features and strengths. Firstly, it adopted a mixed-method approach including both quantitative and qualitative methods. This is valuable since the different methodologies could help to evaluate a program from different approaches and could help to answer different evaluation questions. Their results could also be integrated and triangulated to form a deeper understanding of an evaluation question [14]. Second, even within either the quantitative or qualitative methodologies, different specific methods were adopted. For example, within quantitative methodology, both direct-approach evaluation (CLA⁺) and indirect-approach evaluation (longitudinal survey) were adopted to increase the validity of the research. Within the qualitative approach, focus groups with different stakeholders (students and teachers) were conducted to form a deeper understanding of the program from different stakeholders' perspectives.

How might the evaluation findings tell us whether the five desired graduate attributes have been attained? In this paper, the major findings based on the different evaluation strategies are presented and summarized. The findings are then integrated to answer the question of whether the desired graduate attributes have been successfully achieved.

Different Evaluation Studies in the Longitudinal Evaluation

The longitudinal online survey assessed the longitudinal development of students in the five desired graduate attributes of PolyU in their study of the new four-year curriculum and the GUR. Four hundred and thirty-four participants completed the questionnaire of all four academic years. Two control groups were added in the third academic year, comprising 300 students studying in previous three-year curriculum of PolyU and 300 students studying in a four-year curriculum in a comparable local university based on quota sampling. Four validated instruments were included in the survey, including measures of empathy, positive youth development, learning styles and student engagement [15, 16]. An alignment of different instruments with the five desired graduate attributes of PolyU is presented in Table 2. Findings revealed students' positive changes in four academic years in study of the PolyU four-year curriculum, particularly in the five desired graduate attributes of PolyU. PolyU four-year curriculum participants also performed better when compared to PolyU three-year curriculum participants and participants in four-year curriculum in a comparable local university [17-20].

Table 2. Alignments between longitudinal online survey scales and desired graduate attributes of PolyU

Desired Graduate Attributes	Instruments	Index
Problem Solving	CPYDS	Problem Solving
Critical Thinking	CPYDS	Critical Thinking
Lifelong Learning	CPYDS	Life-long Learning
	NSSE	Higher Order Learning
		Reflective and Integrative Learning
		Learning Strategies
		Quantitative Reasoning
Ethical Leadership	C-IRI	Empathy
	CPYDS	Ethical Leadership
		Self-leadership
Effective Communication	CPYDS	Social Competence
	NSSE	Collaborative Learning
		Discuss with Diverse Other

Note: CPYDS = Chinese Positive Youth Development Scale; C-IRI = Chinese Interpersonal Reactivity Index; NSSE = National Survey of Student Engagement.

Collegiate Learning Assessment Plus (CLA⁺)

Four rounds of CLA⁺ were conducted with four groups of students enrolled in the PolyU four-year curriculum, respectively, in four time points (i.e., before the start and near the end of the 2013-2014 and 2015-2016 academic years) [21]. The CLA⁺ is a standardized online test developed by U.S. Council for Aid to Education measuring an institution's contribution to students' development of problem solving, critical thinking and written communication skills [21]. Findings revealed that students in senior-year group performed significantly better than students in freshman-year and sophomore-year groups in almost all the competences tested by CLA⁺. A paper is under drafting on the findings [22].

Secondary Data Analyses of the Student Feedback Questionnaire (SFQ) Data

Students' subjective outcome evaluation of GUR was conducted through secondary analyses of Student Feedback Questionnaire data obtained in the four academic years. Results revealed that across the four academic years from 2012-2013 to 2015-2016, students had positive evaluation of the GUR subjects based on the general and specific indicators. Students' positive evaluation of some components such as LCR-English has even increased over the four academic years. Findings of some specific academic years have been published [23-28].

Student Focus Groups and Written Qualitative Evaluation

Qualitative evaluation based on student focus groups and written evaluation form was also conducted [29-33]. The focus groups were guided by a protocol asking about students' views about the rationale, teaching methods, implementation and benefits of the GUR. The qualitative evaluation form included students' descriptors to describe the GUR, and their memorable experiences and perceived benefits. Results based on thematic analyses suggested that students in different years had positive views of the GUR, with specific reference to its subject contents, teaching methods, implementation and perceived benefits.

Teacher Focus Groups and Written Qualitative Evaluation

Teachers teaching different GUR subjects were invited to participate in focus groups in four academic years from 2012-2013 to 2015-2016, and in written qualitative evaluation in 2013-2014 and 2014-2015 [34-38]. The teacher focus groups were guided by a protocol inquiring teachers' views of the rationale, subject content, pedagogy, and benefits of GUR subjects. The written qualitative evaluation form included teachers' descriptors of the GUR, and their perceived implementation, challenges, and benefits of the GUR. Results suggested teachers' generally positive perceptions of the GUR, with specific reference to its rationale, teaching and learning, and impacts on students, although few concerns were noted.

Other Evaluation Methods Incorporated (Longitudinal Individual Case Study and Repertory Grid Tests)

The longitudinal case study and repertory grid test were also incorporated in the study. The former traced 42 students' longitudinal development during their study of the four-year curriculum (including the GUR) from freshman to senior year. The latter assessed 100 stratified random sample of senior-year students in terms of their change in indicators of self-identity after the study of four-year curriculum. The longitudinal case study data indicated students' positive personal growth and development of PolyU desired graduate attributes after studying the GUR [39, 40]. The results of repertory grid test also suggested students' positive changes based on different indicators of self-identity. The related data analyses and paper writing are under way. Table 3 summarizes the papers in References section that have been published or under preparation for each evaluation component.

Integration of Findings with Reference to the Desired Graduate Attributes

This part presents the findings related to the development of students under the new four-year curriculum and the GUR at PolyU, with particular reference to the five desired graduate attributes (i.e., critical thinking, innovative problem solving, effective communication, ethical leadership and lifelong learning). For each attribute, results from different evaluation approaches were presented and integrated. Table 4 shows how different evaluation mechanisms provide evidence for the achievement of the five desired graduate attributes.

Table 3. Summary of papers published on the longitudinal evaluation project of the general university requirements (GUR) at PolyU

GUR evaluation component	Paper published (in reference section)
Four-year longitudinal online survey	16,17,18,19,20
Collegiate Learning Assessment Plus (CLA+)	21,22
Secondary analyses of Student Feedback Questionnaire (SFQ) data	23,24,25,26,27,28
Student focus group and qualitative evaluation	13,29,30,31,32
Teacher focus group and qualitative evaluation	34,35,36,37
Longitudinal case study	39,40
Overall evaluation	15,33,38

Teacher focus group and qualitative evaluation	√	√	√	√	√
Longitudinal case study	√	√	√	√	√
Repertory grid test	√	√		√	

Critical Thinking

In the longitudinal online survey, students' ability in critical thinking was assessed by the Critical Thinking subscale of CPYDS. Results showed students' significantly higher ratings of Critical Thinking subscale in the academic year of 2015-2016 than in 2012-2013 and 2013-2014 [17]. Compared with control group 1, i.e., the students studying PolyU three-year curriculum, the experimental group (i.e., the students of PolyU four-year curriculum) scored significantly higher in critical thinking subscale [18], although no significant difference was found between experimental group and control group 2 (i.e., the students in the four-year curriculum in a comparable local university) [19]. Students' critical thinking ability was also

assessed by three subscales of CLA⁺, including scientific and quantitative reasoning, critical reading and evaluation, and critique an argument. Results revealed that senior-year group of students performed significantly better than sophomore-year group of students in all the three subscales indicating critical thinking [22]. Results also showed that the senior-year group of students scored significantly higher in all three subscales than the freshman group of students [22].

The qualitative data based on different methods including student and teacher focus groups, written qualitative evaluation, and longitudinal case study also consistently indicated students' improvements in critical thinking skills through studying different subjects in GUR in different years [13, 31, 32, 34, 35]. Qualitative data also indicated the important role of the interactive teaching and learning methods played in students' critical thinking development. Particularly, group projects and discussion contributed greatly to students' development of critical thinking through confronting them with different viewpoints of their peers [32, 35].

Innovative Problem Solving

Different evaluation data suggested students' improvements of problem solving ability after studying the four-year curriculum and the GUR at PolyU. Students' problem solving in the longitudinal survey was assessed by the Problem Solving subscale of CPYDS. Results demonstrated that students had higher ratings of Problem Solving subscale in their junior and senior years when compared with their freshmen and sophomore years [17]. Although the students of PolyU four-year curriculum performed similar to the students in the four-year curriculum of a comparable local university on problem solving subscale [19], they performed significantly better than the students in PolyU three-year curriculum [18]. Students' ability of problem solving was also measured by the analysis and problem solving subscale of CLA⁺, with the senior-year student group scoring significantly higher than both the sophomore and the freshman groups on analysis and problem solving subscale [22].

Focus group results suggested the positive impacts of the GUR to students' development of problem solving ability [34, 35, 39]. Particularly, the Service Learning subjects were perceived as much helpful to students' innovative problem solving, which provided students with opportunities to solve problems in natural social circumstance through a 40-hour community service practice. Both teachers and students perceived that many unexpected events occurring in service practices promoted students' ability to solve problems innovatively [35]. Some other teaching approaches in GUR such as hands-on workshop in freshman seminar subjects and field work in cluster area requirement subjects also trained students in problem solving ability [39].

Effective Communication

The GUR and the four-year curriculum successfully promoted students' effective communication competencies. Students' effective communication was firstly measured in the longitudinal survey by three subscales, including the Social Competence subscale of CPYDS, and the Collaborative Learning and Discuss with Diverse Other subscales of NSSE. Comparing students' performances in the four academic years, students' ratings of Collaborative Learning and Discuss with Diverse Other subscales in the academic years of 2014-2015 and 2015-2016 were significantly higher than those in 2012-2013 and 2013-2014, although their ratings of Social Competence subscale remained stable [17]. The PolyU four-year curriculum students also performed better than the PolyU three-year curriculum students

in collaborative learning and discuss with diverse other subscales, while no significant difference was found between their performance of social competence subscale [18]. The PolyU four-year curriculum students performed comparable to the students studying four-year curriculum in a comparable local university on all three subscales [19]. Students' competence in effective communication, particularly written communication, was also measured by two subscales of CLA⁺ (writing effectiveness and writing mechanics). Comparison of students' ratings between different groups showed that the senior-year group performed better than the sophomore group in writing mechanisms and the two groups had no significant difference in their ratings of writing effectiveness [22]. The senior-year group also performed better than the freshmen group in writing effectiveness, while the two groups performed similar in writing mechanisms [22].

Besides, focus group and written qualitative evaluation results in different academic years suggested that the students' development in written communication skills were effectively strengthened by students' study in language and communication requirements, particularly English-LCR subjects [30, 32, 34-36, 39]. Through English-LCR subjects, students were effectively taught how to integrate and critique different sources and viewpoints in writing academic essays, and how to structure academic articles and cite references [35, 36]. Some cluster area requirement subjects with English reading and writing requirements also effectively trained students' ability in effective written communication [36]. Some students perceived the cluster area requirement subjects with reading and writing requirements as highly useful because these subjects offered them opportunities to get individualized instructions from English tutors about their academic writing assignments [30, 32]. Besides, students' oral communication and public expression skills were promoted through studying in different group projects and group presentation tasks, which built up students' confidence in oral communication and increased their ability to communicate with people from different backgrounds and disciplines through group projects [30, 32, 35, 39].

Ethical Leadership

Students' ethical leadership was measured in the longitudinal survey by three subscales: Empathy subscale of C-IRI, and Ethical Leadership and Self-Leadership subscales of CPYDS. Results showed that students' rating of empathy in their sophomore year decreased when compared with their rating in freshmen year; their ratings of ethical leadership decreased in sophomore year but rebounded in senior year; and their rating of self-leadership in senior year was higher than in sophomore year [17]. The PolyU four-year curriculum students, i.e., experimental group, scored significantly higher in empathy and ethical leadership than the PolyU three-year curriculum students (i.e., control group 1), although the two groups performed comparable in self-leadership [18]. The experimental group and control group 2 (i.e., the students studying four-year curriculum in a comparable local university) performed similar in empathy, ethical leadership and self-leadership [19]. Qualitative evaluation results indicated students' improved understanding of leadership concepts and development of leadership skills through studying GUR subjects, particularly the leadership and intrapersonal development subjects. First, the leadership and intrapersonal development subjects, particularly the tomorrow's leaders subject, promoted students' understanding of leadership attributes, particularly concept of self-leadership [35, 36, 39]. Some students could be able to apply the leadership attributes learned in leadership subjects in their daily life in interpersonal relationship building [13, 39]. Besides the leadership

subjects, the service learning subjects cultivated some students' empathy and social responsibility, which are important components of ethical leadership [34-36]. Furthermore, different group project works in different GUR subjects created good platforms for students to practice their leadership skills [32].

Lifelong Learning

Different evaluation studies also suggested students' improvements in lifelong learning ability. Students' ability of lifelong learning was assessed by the lifelong learning subscale of CPYDS, and four subscales of NSSE, including higher-order learning, reflective and integrative learning, learning strategies, and quantitative reasoning in the longitudinal survey. Results showed that students' ratings of higher-order learning, reflective and integrative learning and quantitative reasoning in the academic years of 2013-2014 and 2014-2015 were significantly higher than their ratings in 2012-2013 and 2013-2014 [17]. Students' ratings of learning strategies in 2014-2015 and 2015-2016 were significantly higher than that in 2013-2014 [17]. The experimental group scored higher than the control group 1 on higher-order learning, reflective and integrative learning and learning strategies, while the two groups had no difference in their ratings of lifelong learning and quantitative reasoning [18]. The experimental group also performed better than control group 2 on learning strategies, while the two groups performed similar on lifelong learning, higher-order learning, reflective and integrative learning and quantitative reasoning [19]. These results generally suggested students' improvements in lifelong learning ability over their four-year study, particularly in higher-order learning, reflective and integrative learning, learning strategies and quantitative reasoning.

Qualitative evaluation findings were also positive, suggesting that the GUR was conducive to students' development in lifelong learning capacity. Perceived by students, some cluster area requirement subjects promoted their interests in learning some topics beyond their fields of specialized studies [30]. These students had intention to further study these topics if there were opportunities. The sports-training courses in HLS component also nurtured some students' interests in further learning and doing these sports, and developed in these students a notion of pursuing healthy lifestyle. In addition, some assessment methods such as written assignments adopted in many GUR subjects promoted students' ability of lifelong learning through facilitating students to search literature and accomplish their writing tasks independently [32].

DISCUSSION

This paper reported findings of a five-year longitudinal evaluation project on how the new four-year undergraduate curriculum and the "General University Requirements" (GUR) contributed to students' development on the five desired graduate attributes of The Hong Kong Polytechnic University (PolyU). Results from different evaluation mechanisms, including longitudinal online survey, collegiate learning assessment plus (CLA⁺), Student Feedback Questionnaires (SFQ), focus groups with students and teachers, written qualitative evaluation, and longitudinal case study, consistently suggested that the four-year curriculum

and the GUR were effective in promoting students' development in the five desired graduate attributes.

These findings have two general implications. Firstly, although the curriculum reform and the introduction of general education in higher education of Hong Kong are significant, fewer studies have been conducted to evaluate the effectiveness of these reform initiatives. Since general education was mainly a heritage of Western, especially American higher education, whether its curricular models adapt to Hong Kong context with a Chinese cultural heritage and a heritage of British model of higher education should be investigated. Actually, some scholars raised their worries about the adaptation of general education to the context of Hong Kong [11, 41]. They doubted the effects the new curriculum with a significant component of general education in Hong Kong higher education. The findings of the present evaluation study challenged these doubts by showing the effectiveness of the GUR curriculum and the new four-year curriculum of PolyU in cultivating students' desired graduate attributes of PolyU.

Secondly, findings of the present study indicated that teaching and learning design plays an important role in aligning general education with desired graduate attributes. Literature also suggested that active learning strategies such as group-based learning with authentic tasks, game-based learning, and written assignments are highly helpful in helping students to develop desired graduate attributes such as critical thinking and effective communication [42-44]. Scholars promoting general education movements in American higher education also advocated that general education reform should pay more attention to teaching and learning methods than focusing solely on curricular content of general education [45]. The findings of the present study are in line with the existing literature by showing that the active pedagogy adopted in GUR subjects was highly effective in promoting students' development of the desired graduate attributes.

The present study has several limitations. First, the longitudinal survey only included the control groups in one academic year (i.e., 2014-2015), which could not compare group effects over time. Second, since participants in control group 2 also studied a general education program in a comparable local university which might have similar effects as the GUR, the effects of PolyU new four-year curriculum comparing to the old three-year curriculum could not be fully tested by comparing the experimental group and control group 2. Third, the four groups of participants participating in four rounds of CLA⁺ were not the same participants, which also limited the interpretation of the results. Despite of these limitations, this present comprehensive evaluation research is pioneering in Hong Kong in evaluating the effectiveness of the new four-year curriculum and general education program of PolyU in promoting students' development in the five desired graduate attributes.

ACKNOWLEDGMENTS

ABSTRACT

Through focus group interview, this chapter explored teachers' perceptions and experiences of the general university requirements (GUR) in the new four-year undergraduate degree program of The Hong Kong Polytechnic University in Hong Kong. A total of 52 colleagues involved in teaching and coordination work participated in focus group interviews. Eight focus group sessions were formed to understand the views of teachers on the eight GUR curriculum components. Results showed that teachers generally had positive views of subject content as well as student learning and engagement. Teachers also demonstrated deeper understanding of teaching with active involvement. Teachers also had gained multidisciplinary working experience through

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

teaching GUR subjects. Teachers perceived their subjects and related teaching as beneficial to students' all-round development, particularly in communication, critical thinking, confidence and self-esteem.

INTRODUCTION

Teachers play a vital role in educational activities. Some scholars [1] depicted teachers as "change agents" of curriculum reforms. Gaff [2] argued that even the well-designed curriculum could not ensure student learning if there were no effective teachers. Empirical studies consistently suggested that teachers' attitudes and beliefs had significant influence on curriculum implementation. For example, teachers' positive attitudes towards curriculum content could facilitate curriculum implementation, and their beliefs about teaching could influence their teaching practices as well as student learning, motivation and achievement [3-5]. In addition, actual implementation of education reforms and effects of such reforms depend heavily on teachers since different teachers may interpret new policies differently due to different beliefs and experiences, student characteristics and working contexts [6].

With regard to general education in higher education, the role of teachers is particularly critical. In reviewing general education status in American higher education and advocating further reforms, Gaff [7] proposed that in addition to curriculum content, the teachers as one critical element had to be considered. Particularly, Gaff [7] suggested that it was imperative to examine general education teachers' motivation, barriers to their teaching, and their strategies for successful implementation of general education curriculum. French [8] argued that the role of teachers was particularly important in general education than in specialized education since students' motivation was lower in general education than in specialized education. Hence, teachers' art of teaching, their understanding of student needs and adoption of teaching strategies would be very important for engaging students in general education learning process.

Although the significant role of teachers in general education was recognized, there were fewer empirical studies conducted in this area. Gaff [9] observed that "when the revival of interest in general education began, attention focused almost exclusively on content" and "little attention was given to the teacher and strategies for teaching." A review of existing literature found that teachers' experience and views were only mentioned in a marginalized place in many reports and studies on general education reforms. Even within this limited literature, there were inconsistent findings. For example, Tobolowsky, Cox and Wagner [10] examined faculty's perceptions of freshmen seminar in a university in the United States. The freshmen seminar was designed to foster freshmen transition to university life. The content included time management, study strategies, academic integrity, university understanding, and career planning, etc. The survey found that through teaching the seminar, the majority of teachers perceived that they were more enjoying and engaged in teaching, understood more about student needs, and met more colleagues outside their own disciplines.

However, many other studies reported teachers' negative attitudes towards and experiences of general education courses and their frustrations in teaching these courses. For example, a study [11] on undergraduate curriculum reform in a renowned Chinese university to promote general education showed reluctance of faculty in teaching general education subjects. Many faculty members perceived teaching general education subjects as challenging

and time-consuming because they had less experience in teaching these subjects and the teaching was not helpful to their own research and promotion. Similarly, in many American universities, teaching staff of general education subjects was normally “borrowed” from specialized departments [12]. Therefore, these staff had low loyalty to and little concern about general education subjects and was unaccustomed to teaching these subjects [2, 12].

Similar observation was also reported by some scholars on recent curriculum reform in higher education in Hong Kong that transferred its three-year to four-year curriculum and developed a significant component of general education in new curriculum. For example, Hoshmand [13] argued that some academic staff in universities in Hong Kong perceived teaching general education subjects as time-consuming and worthless since they were more research-oriented and their promotion depended more on their research achievements. Also, since many faculty members were educated under the previous three-year specialized structure of undergraduate education in Hong Kong, they might have less understanding of general education and its related teaching. For example, Hoshmand [13] argued:

“the faculty (in Hong Kong higher education) has not experienced General Education in their undergraduate studies and has difficulty stepping out of their comfort zone to offer the courses that integrate knowledge across the disciplines. They also have a wrong assumption about the nature of the General Education courses. Often they think that a GE course is similar to an introductory course in a discipline. This alone is a major barrier to change.”

The above literature sheds light on how teachers perceive and experience general education. However, there are few empirical studies in this area. Also, although some studies explored teachers’ positive or negative perceptions, they did not reveal why teachers had related perceptions and what factors contributed to their perceptions. Furthermore, there were fewer studies that explored teachers’ perceptions and experiences in general education in a comprehensive manner. Finally, no study has to date been conducted to understand the views of teachers of general education within the context of an education reform.

Against the above background, the present study examined teachers’ perceptions and experiences of a new general education program, “General University Requirements” (GUR), in the new four-year undergraduate curriculum of Hong Kong Polytechnic University (PolyU) in Hong Kong. Since the 2012-2013 academic year, PolyU transformed its undergraduate degree program from three to four years. As an integrated part of the reform, the GUR was introduced as a significant general education component of the new four-year curriculum of PolyU. The GUR attempts to develop students in the five desired graduate attributes, including effective communication, critical thinking, innovative problem solving, lifelong learning, and ethical leadership. The GUR was formally implemented in the 2012-2013 academic year. It adopted a more active and interactive pedagogy. The curriculum had six major components, as introduced below.

- *Freshman seminar (FS: 3 credits)*: A FS subject is offered by each faculty/school to all freshmen enrolled in the faculty/school. FS introduces freshmen to their disciplines and potential majors. It also develops students’ entrepreneurship, higher-order thinking, and self-directed learning.
- *Leadership and intrapersonal development (LIPD: 3 credits)*: Two subjects are offered in LIPD component. They are “Tango! Managing self and others” (“Tango!”) for students in Faculty of Business, and “Tomorrow’s leaders” (TL) for students in

other faculties/schools. LIPD nurtures students' understanding of theories on inter- and intrapersonal qualities of leadership and develops their self-awareness and self-reflection skills.

- *Language and communication requirements (LCR: 9 credits)*: LCR includes English LCR (6 credits) and Chinese LCR (3 credits). LCR attempts to cultivate students' language and communication proficiencies in both Chinese and English.
- *Cluster area requirements (CAR: 12 credits)*: In CAR, each student is required to study at least four subjects, with each subject being selected from each of four cluster areas, namely "CAR A: Human nature, relations and development," "CAR B: Community, organization and globalization," "CAR C: History, culture and world views," and "CAR D: Science, technology and environment." Among the four subjects studied, three additional requirements should also be fulfilled. They are China studies requirements (CSR), English writing and reading requirements (EW/ER) and Chinese writing and reading requirements (CW/CR). CAR attempts to expand intellectual capacities of students beyond their majors and develop their written communication proficiencies in English and Chinese as well as understanding about China.
- *Service learning (SL: 3 credits)*: Each student is required to take one SL subject with a significant service component. SL attempts to help students apply academic knowledge into practice, help them reflect on their roles as professionals and citizens, and develop their empathy for people in need.
- *Healthy lifestyle (HLS: non-credit-bearing)*: In HLS, students need to complete four components of courses including introductory lecture, sports training/participation, e-learning, and wrap-up lecture. HLS attempts to help students to master important knowledge and skills contributing to healthy living and wellbeing.

In view of the important role of teachers in general education and the fact that there are few studies in this area, this study attempted to explore teachers' perceptions and experiences of the GUR subjects at PolyU. The study is meaningful not only for gaining knowledge of implementation of the GUR and its future improvement, but also for shedding light on teacher views of general education in the broad literature. The present study belongs to a comprehensive evaluation project of the GUR starting from the 2012-2013 academic year. Different evaluation components were implemented in the project, including objective outcome evaluation, subjective outcome evaluation, and qualitative evaluation. In qualitative evaluation, teacher focus groups and student focus groups were conducted in each academic year. This study is based on the teacher focus groups conducted in the 2014-2015 academic year.

OUR STUDY

Participants were 52 staff members who were involved in subject teaching or coordination in different components of the GUR curriculum in the 2014-2015 academic year. These staff members were recruited based on purposeful sampling through the nomination of program leaders or key teachers in different GUR components. These staff members participated in a focus group interview at the end of the second semester of the 2014-2015

academic year. Eight focus group sessions were conducted based on eight GUR curricular areas. These sessions included FS (n = 7), LIPD-TL (n = 8), LIPD-“Tango!” (n = 1), English LCR (n = 8), Chinese LCR (n = 8), CAR (n = 8), SL (n = 6), and HLS (n = 6). Since the subject “Tango!” only had two teaching staff, and one staff member was on leave during the focus group period, this session only had one participant. Each session was conducted by two experienced researchers. One served as the moderator and the other served as the observer. All the sessions lasted for one to two hours.

Focus Group Protocol

A focus group protocol was developed by the authors to guide the focus group interview. It included a set of guideline questions aiming to explore teachers’ perceptions and experiences of the GUR subjects they taught. The key questions included:

- What is your understanding about the GUR and its significance to PolyU students?
- Please describe the changes you have witnessed from the students attending your GUR subject.
- Could you suggest any particular component(s) of your GUR subject that is associated with the positive/negative feedback from your students?
- How would you comment the support, communication channel, and collaboration from your counterpart? To promote the effectiveness, what kinds of support would you suggest?
- In your perspective, what are the major challenges in the implementation and goal-alignment of the GUR curriculum?
- What is your perception of the alignment of your component of GUR subject with PolyU desired graduate attributes, and with intended learning outcomes of your GUR component?

All the focus group sessions were audiotaped and all audio files were fully transcribed into the texts. Method of framework analysis [14] in qualitative data analyses was adopted. Firstly, one researcher quickly read all the transcripts for twice to familiarize herself with the data and identify key ideas and important themes. The key ideas and major themes were then organized to form a thematic framework for further coding. Secondly, the researcher read all transcripts again to carefully code all data in detail under the thematic framework. During the coding process, the thematic framework was also revised based on the researcher’s enriched understanding of the data. Based on the coding, interpretations and explanations about the data were formed.

FINDINGS

Teachers generally developed a deep recognition and appreciation of the rationale underneath the design of different components of the GUR. For example, for the design of LCR component that offered different language subjects to students with different levels of

language proficiencies, LCR teachers developed deep understanding and recognition of the rationale of the design. This can be illustrated by one ELCR teacher's narratives below:

"One important difference is that ELC (English Language Center of PolyU which is responsible for offering the English LCR subjects) is now streaming students based on their DSE (The Hong Kong Diploma of Secondary Education) results. I teach one of the high-level (ELCR) courses to students with the DSE English exam score above grade 'five.' And I am totally impressed by their standard of English, sort of their native speakers' standard. So, I'm not actually teaching them English in terms of grammar. I'm teaching them 'persuasive communication,' which is the name of the course they haven't done before. So I think it is good to let higher level students to get something specially designed for them, which they didn't get in the old curriculum."

In some components such as CAR where teachers might have more freedom in designing their subjects, some teachers explored how to design their subjects to cater for the learning needs of students from other disciplines. For example, a teacher teaching a subject in science area of CAR component expressed:

"The subject I taught is *Chemistry in Everyday Living*. In case students had weak mathematical and physics knowledge backgrounds, I taught my subject in a simpler way, mainly focusing on developing students' appreciation of chemistry. ...The subject also had experimental classes. The students were very excited in these classes."

Some teachers consciously arranged their subject teaching around "hot topics or themes in real world" or themes that had immediate concern to students' life. Through this, the teachers intended to have students relate the knowledge they learned from the class closely with the outside world, as a teacher teaching a Chinese LCR subject expressed in the following way:

"For our Chinese LCR subjects, we base our teaching on some contexts that are related closely to the critical issues in current society. Some critical issues include issues related to Hong Kong medical insurance system and environmental protection. Based on these issues, we conduct some language training. In such a way, students would not only gain knowledge about Chinese language, but also relate the knowledge to the real world."

In some components, teachers developed a much richer understanding of the functions of their components than those set by the University. Teachers also wove their understanding into their subject design and teaching. For example, according to the guideline of the University, the aim of the Chinese LCR component was to enhance students' language proficiency in Chinese. However, the CLCR teachers understood the function of CLCR at a richer level. They perceived that Chinese subjects, if designed well, could not only foster students' language and communication competence but also cultivate their ability of critical thinking and problem solving. These teachers implemented this understanding in the subject design and implementation of CLCR. This can be illustrated by two CLCR teachers' narratives below:

"Actually our assessment methods are also diversified. We are not developing one approach of thinking but hope to have students to think issues from multiple perspectives. So we incorporate role play in assessment of our subjects. During the role play activity, students learn to deal with some problems. This would be helpful to students' critical thinking and problem solving."

“Many people may think the training of Chinese is not important in the university level. Actually, Chinese is most students’ first language. When these students are thinking, they are using Chinese. Hence, while the University set the goal of this component (CLCR) as language skill training, we think these subjects could achieve more outcomes, including communication, problem solving and critical thinking. Therefore, it seems that we are doing language training on the surface but in fact we are doing more. This is also the value of our subjects.”

Teachers’ narratives also indicated that for teachers in certain disciplines such as Chinese language, the GUR or general education served as an opportunity for them to re-claim the value and legitimacy of their disciplines in university community and in contemporary society.

Opportunities and Challenges in Teaching Interdisciplinary Subjects

Although teachers generally had positive views about rationale of GUR and its subject design, their views on Freshman seminar which incorporates knowledge from multiple disciplines and team-based teaching were diversified or even bi-polar.

For a few teachers, FS subject served as an opportunity for them to explore interdisciplinary teaching that they seldom experienced before. For example, in one faculty, in order to engage students who came from different disciplines of the faculty and develop students’ interdisciplinary understanding, the staff members of the faculty designed the FS subject content to center on common issues in real world to solve which multidisciplinary knowledge should be utilized. The staff members also incorporated innovative teaching and learning methods in the subject. This was mentioned by one teacher as below:

“Sometimes it’s a bit hard to pick a topic that of interest to every student because we have four departments [in our faculty] and we have a lot of students with different natures. So that’s why we try to pick a theme on environmental protection that is an issue and challenge that students will face when they finish their study and work as professionals. So that’s why in the first lecture what I do is to give them a general message about what is the environmental problem we encounter in construction industry. And then we have another three lecturers from other departments to talk about different things.”

Another staff member who was involved in designing the same FS subject in the same faculty talked about the incorporation of site visit as another important approach in the subject to engage students in interdisciplinary learning. He said:

“But the site visit is very good, right? Because like Disney, we can go there, and it can explain the construction from civil engineering, building management, and there are many hotels in the Disney, and then building services, LSGIS (land surveying and geo-informatics), and some sorts of very small parts. So by doing site visit, they...the students...even they come from different disciplines, understand what they will be and how they will be collaborating after graduation.”

However, for staff members from some other faculties, they designed and delivered the FS subjects in their faculties in a different approach that mainly invited teachers from each discipline to give introductory speeches on their respective disciplines. These staff members encountered a failure in the design and implementation. They observed lower engagement of students in their FS subjects because many students did not have much interest in understanding knowledge of other disciplines and could not perceive the linkage between other disciplines and their own disciplines. Defeated by this effect, staff members from these

faculties perceived that the University should fine-tune FS subject to make it more department-based rather than faculty-based.

Teaching Promoting Active Learning and Student Engagement

Teachers commonly viewed that students liked many active teaching and learning methods adopted in different GUR components, including group project, fieldtrip, and experiential learning. The reason perceived by teachers was that through these methods students learned more interactively and diversely. Students also gained “autonomy” and “initiative” in planning and directing their own learning. These all promoted students’ motivation in learning. For example, two teachers shared in the focus group respectively:

“So I think, interview they (students) like it, site visit they like it. I think group project they like it. You know, they are interacting with a different group, and many times they are not from homogenous group. [This is] quite different. [Students come from disciplines of] business, technology and designs. So they work together. ... I have to say [the learning is] more like a play, learning from a play.”

“(when the teacher was asked about whether students enjoyed the group work on interviewing successful people in different industries in the ‘Tango!’ subject) Yes, they do, because they are actually getting their full freedom, you know, of choosing their own topic, of choosing the person to interview, of choosing the business they interview. So we suggest them that for example if you study logistics and maritime, maybe [it] would be good to interview someone from this area, from this business you want to enter anyways. You know, if you want to be this person, we might want to know what it takes to take this position. And so I think some of them put this assignment through seriously, then they benefit a lot from that.”

Some other teachers teaching SL subjects observed their students’ attitude changed from “not enjoyed” to “enjoyed” in studying SL subjects. They thought that SL subjects made students feel that they were capable of “doing something to the society” and developed students’ “sense of achievement and sense of meaning” through learning. For example, a teacher teaching a SL subject shared:

“Based on our observations of students, we all agree that students enjoy very much the service process. However, at the very beginning of the subject, a number of students were having great reluctance. They probably felt ‘I was forced to come’... Then when it came to the later stage of the subject, they might feel ‘well, I could make some change.’ So they were enjoying. I think we could all feel that in the later stage students might have realized what they were doing, such as ‘I have helped people’, even though they were much unwilling at the very beginning. So we changed their minds and made them enjoy.”

In addition to teachers’ perceptions of the impact of active teaching and learning on students, a few GUR teachers were going deeper to have talked about their deep teaching philosophy and how they implemented this philosophy in teaching practice. In these teachers’ philosophy, teachers and students were equal in the learning process and they worked together to construct students’ learning. Therefore, these teachers supported very much the active learning approach and implemented this approach in their teaching. This can be illustrated by the following two narratives:

“Um, I hope that they (students) become overall much more open, because I noticed many students... because we especially have most first year and second year students...they come in right from secondary schools and have the attitude that teacher is the big hierarchical figure that they cannot question; and they can just sit there silently listening and looking, [but] not disturbing. And I am trying to break through this [kind of]

thinking, because I am telling them that, ‘You know, we are on the same level. If I say something that you don’t agree with, you need to tell me. You know, you need to ask questions.’”

“In each term, I would bring students out to do field work. Sometimes we went to museums. Sometimes I watched movies and chatted with students. From their feedbacks, students said the fieldwork made them learn a lot, read more books, and know more things. ... Even in the class, I would also ask them questions every ten or fifteen minutes. This contact with teacher is very important. Through this, I want to have them be more confident. Many students thought that they could find answers through the Internet. However, the interaction between students and between students and teachers would be something beneficial to their whole life.”

While teachers commonly observed students’ deep engagement and active learning in GUR curriculum, they also expressed that there were two factors hindering students’ engagement. The first factor was students’ utilitarian attitudes towards their university study, as elaborated by one teacher that “For some students, they were very ‘strategic’ in their university study. When they saw that their four-year curriculum had so many requirements, they only wanted to take, take, take, and to get these subjects done as fast as possible.” Students’ less serious or indifferent attitudes towards their GUR study had defeated some teachers’ passion to teach GUR subjects.

The other factor was that students were “too busy” under the new four-year curriculum structure. This made some students had no time and energy to study their GUR subjects carefully and attentively, as expressed by one teacher in the following way:

“The situation I have seen was this: for these students enrolled in the new four-year curriculum ... the thirteen-week long semester course would be very harsh and they also need to take CAR subjects. So they made themselves very busy. So they had no choice but to cope with these subjects hastily. So instead, I feel that I sympathize with them.”

Challenging but Joyful Inter- and Intra-Disciplinary Collaboration

The teaching in the GUR provided opportunities and joyful experiences for multiple kinds and levels of collaboration among teachers, in a disciplinary and interdisciplinary manner. This was generally valued and appreciated by teachers for providing opportunities for them to extend their horizons. For example, in coordinating FS subject teaching in some faculties, the academic staff developed feelings that although coordinating staff members from different disciplines to collectively teach FS subject was quite a challenging task, the process gave them valuable and joyful interdisciplinary work opportunities and experiences. This was shared by one staff member below:

“I am a coordinator. I don’t teach the Freshmen Seminar. I coordinate all the tutors, all the departmental representatives (teaching FS subject). I think this kind of Freshmen Seminar is quite, in the very beginning is very challenging because it is quite diverse. We have to cooperate among different departments, and chase after everybody on proposing [teaching] project and schedule, whatever. But then it turns out that it is quite joyful experience, because I have the chance to mix with other departments’ colleagues. Otherwise I would never work with them, even in the same faculty. I know more people at least.”

In addition to gaining interdisciplinary working experience, the teaching in the same GUR component promoted some teachers’ interaction and mutual learning with their fellow colleagues within the same department. For example, one teacher in ELCR and another teacher in LIPD component noted respectively:

“There is one good thing about all (ELCR) subjects actually. [It] is that, um, like I taught PEUS (one ELCR subject) and you taught AEUS (another ELCR subject), and then, there is an area we call it the ‘teacher area’ where we have lots of notes and supplementary materials that we can use. And they are developed and contributed by colleagues voluntarily and then they are all good stuff.”

“(One LIPD subject teacher was talking about another senior colleague teaching the same LIPD subject) Oh, it is really great, really great. She is a great professor. So what we are doing is that we are so responsible for the lectures. But she is always asking me for some inputs or having any comments or suggestions. She is always willing to actually incorporate them in the whole material. And for the tutorials, actually she gives me ‘green light’ to do almost anything. Actually in the seven semesters what we did was that I was more or less developing the contents and then she would just follow my suit. So I found it very very very good.”

Positive but Belated Effects on Students’ Development of Competences

Teachers perceived that their teaching in GUR has promoted students’ positive development in different skills and competences. The first competence was effective communication. For example, some teachers from CAR, ELCR and LIPD components perceived that through their subject teaching and paper writing assessment, they observed their students’ increased confidence and self-esteem in English writing skills, as well as a strong sense of achievement in academic writing. This can be illustrated by the following two narratives:

“For the writing requirement, we do see improvements in confidence, and that was what students told us during the focus group meetings. So I can’t comment on the improvement in language but I think they are more confident to tackle a bigger piece of writing. So, I think that is quite important.”

“Term paper writing is a very good training. Particularly for students in some disciplines, which did not have much writing tasks, they said ‘wow, this is the first time that I have written so many things.’ Particularly for some students upgraded from Associate Degrees, they directly felt ‘it is so good to do this.’ After doing this, they even did not care about their grades. They felt ‘oh, I have achieved something.’ Their self-esteem has been improved a lot and they would not be afraid of writing.”

In addition, there were teachers who consciously promoted frequent group discussions or free expressions of their students in classes. They observed students’ improved confidence in presenting ideas in public through these methods. This can be illustrated by the following narrative of a teacher:

“After this course, I collected some feedbacks from our students. They commonly reflected that they had become bolder in public expression because of the many discussions in tutorial sessions. Maybe in some faculties such as business, there were constant group discussions or presentations. However, for students in department of engineering or other disciplines, it might be hard for them to express their ideas in public. At the very beginning of this subject when they did not know each other, they were unwilling to speak. But I used a lot of methods to evoke their expression, which made them feel that they became more confident in public speaking after they completed this subject.”

Apart from the above-mentioned skills, teachers perceived that some of their students gained improvements in their higher-order thinking ability, also through the active learning practices. For example, one teacher teaching a LIPD subject perceived that her subject promoted students’ multi-perspective and critical thinking through peer influence fostered by group discussion and peer sharing in the classes:

“One point I want to add is that students developed multi-perspectives, because when they were doing some sharing, they found that their peers had different stories. Then they would refer to the experiences of their peers, whose effect was bigger than what we have told them. So the peer influence is more significant, which made them have more multi-perspectives and critical thinking such as ‘what is it exactly? In the moment, am I inside the box? Or could I think out of the box?’ So they gained many experiences from peer learning.”

Furthermore, some teachers believed that the impacts of individual GUR subject existed but might not be visible in a short time. They believed that each GUR subject served as a piece of an integrated whole to contribute to students’ holistic development. Some teachers depicted the function of the GUR as “sowing a seed,” while others perceived that all GUR subjects, together with students’ other educational experiences such as internship, and students’ life experience, served as a whole to shape students’ all-round development at PolyU.

DISCUSSION

The present study is among the few to explore teachers’ views and experiences about general education curriculum in higher education settings, particularly in contexts of Hong Kong. In view of important roles that teachers play in general education, this study could add significant contribution to the existing limited literature on teachers’ perspectives of general education.

Several major observations could be generated from the findings. First, teachers teaching different subjects in GUR generally supported the rationale and subject design of their respective GUR components. Some teachers even consciously designed their subject contents and teaching to be around important issues in contemporary society, to promote interdisciplinary learning, and to meet student needs better. This demonstrated teachers’ deep understanding of and engagement in general education teaching. This observation challenged part of the existing literature that suggested teachers’ lower engagement in general education teaching [13, 15]. This might be explained by the application- and practice-oriented culture of PolyU. Newton [15] argued that in institutions that had a more entrepreneurial-oriented culture and whose mission was more sensitive to outside needs, faculties and general education courses might be more responsive to students’ needs and more influenced by students’ aspirations. A practical-oriented culture in PolyU might have made teachers more sensitive to changing requirements of the society and student needs; and therefore more devoted to general education teaching and subject design that were deemed important for contemporary society. The finding was also in line with the previous studies based on teacher focus groups and qualitative evaluation, which showed that teachers of different GUR subjects generally understood and supported the rationales of the GUR [16, 17].

Secondly, teachers commonly perceived that the GUR subjects with a variety of active teaching and learning methods such as service learning, group project, and writing assignment were effective to engage students in deep and active learning. Not only this, some teachers consciously designed their subject content and teaching based on their educational philosophy to promote students’ active, interactive, and interdisciplinary learning. The views and actions of teachers also indicated GUR teachers’ deeper understanding of general education and active participation in teaching and learning, which challenged the current mainstream of

literature suggesting that most teachers were lack of experience and enthusiasm in general education [2, 11-13].

Thirdly, some teachers gained quite valuable interdisciplinary working experiences from teaching the GUR subjects. The GUR teaching and subject coordination in some subjects offered teachers new opportunities to work with fellow colleagues outside of their own disciplines. The finding suggested that teachers appreciated and valued these “fence-breaking” experiences. This finding supported the current limited literature suggesting that some general education subjects such as first-year seminar promoted professional partnership among teaching staff across different disciplines [18].

Fourthly, teachers perceived positive impacts of the GUR on the holistic development of students. These impacts included the development of students’ sense of achievements, confidence and their increased self-esteem. They also included students’ improvements in oral and written communication, and critical thinking skills. Teachers perceived that one major factor contributing to students’ positive change was the active teaching and learning methods adopted. This was supported by the literature that teachers’ instructions promoting active and interactive learning could foster students’ growth in important competences such as thinking, communication, problem solving, cognitive skills, etc. [19, 20]. These views are also consistent with the findings of other evaluation studies of the GUR [21, 22].

Furthermore, challenges in teachers’ teaching of the GUR subjects were also identified. One major challenge was the design and teaching of subjects with an interdisciplinary nature such as FS subject. One major reason was that many staff members were educated under the previous British structure of higher education that stressed early specialization and strict division of academic disciplines. They may get less chance to experience interdisciplinary teaching and learning [13]. Meanwhile, teaching interdisciplinary subjects were also a world-wide challenge in general education since the over-division of knowledge and disciplines in modern universities greatly hindered this kind of teaching and it was more and more difficult to find interconnections and common understanding among different disciplines. Another challenge was some students’ unserious and utilitarian attitude towards their study in GUR. This phenomenon has also been noted by the literature [15, 23], which suggested that some students viewed general education requirements as obstacles to overcome since they wanted to focus more on their major studies. Findings from the present study further enriched the existing literature by showing that students’ utilitarian attitudes towards their GUR study might be partly caused by their increasingly packing undergraduate study in contemporary society.

Despite the challenges, the present study in general suggested teachers’ overall positive perceptions and experiences of the general education program in the new four-year curriculum of PolyU. The findings are also consistent with the existing literature [24-26]. In view of the shortage of scientific literature in this area, the present study contributed significantly to literature on teachers’ views and experiences of general education in Hong Kong contexts.

ABSTRACT

The general university requirements (GUR) at The Hong Kong Polytechnic University (PolyU) is an integral part of the new 4-year undergraduate curriculum. To evaluate GUR, a longitudinal case study involving 42 cases from different faculties/schools was conducted, with several interviews conducted with the informants over time. The present article is to report the findings of the second year evaluation. Three major observations on students' views about the effectiveness of GUR study were generated from the study, including 1) broadened horizons; 2) increased awareness of the connection between GUR study and all-round development and 3) urge of linking GUR components with one's profession. The longitudinal case study findings suggest that students generally had fruitful learning experiences in GUR study. This study helps to paint a more complete picture of students' views toward GUR and their personal development.

INTRODUCTION

University students' lives are becoming increasingly pressurized due to higher parental and societal expectations as well as rigorous educational changes or reforms in Western and Asian countries [1-3]. The major stresses for university students are commonly related to academic, relationship and financial difficulties [4]. The onset of psychological distress often upsets the fulfillment of different developmental and educational needs. The growing of psychological disturbance amongst students in higher education has called for concern of the scholars and healthcare professionals and a body of research investigating university students' psychological well-being has increased in recent decades [1, 2, 4]. Although there is an increasing concern for university students' development in the higher education fields, one under-researched area is to examine the major transition from their high school to higher education and how the well-being of university students' changes throughout the years in the university [2, 4]. Hence, studies on how universities assist students to adapt to the higher education and longitudinal research on the temporal changes of students' holistic development and their well-being are indispensable.

Given the challenges of globalization and international competitions in the new century, numerous educational reforms and initiatives have been carried out in the Asia-Pacific Region [5] including Hong Kong. In the past two decades, there have been "large-scale changes in nearly every key aspect" of the education system in Hong Kong [5, p.7]. One notable change is to change the senior secondary education and higher education system from the existing British system (3 years of junior secondary +2 years of senior secondary +2 years of matriculation +3 years of university) [3 + 2 + 2 + 3] to a new academic structure (3 years of junior secondary +3 years of senior secondary +4 years of university) [3 + 3 + 4], known as the "3-3-4 reforms". The "3-3-4 reforms" are intended to promote the future competitiveness of Hong Kong university graduates in the global knowledge economy and align "Hong Kong's educational pipeline with those in the Chinese mainland, the United States and the European Union" [3]. However, entry to university "one year younger" in the new academic structure has aroused concerns regarding students' transition from secondary school to the higher education and institutions have focused their efforts on designing the first-year curriculum to assist students to have a smoother transition [6].

Although the 3-3-4 reforms imposed much pressure on teachers and students of the secondary schools, the reforms were perceived as "an opportunity to grow" with numerous new educational initiatives in the higher education in Hong Kong [3]. The previous three-year undergraduate degree program exclusively focusing on disciplinary-specific training is changed to a four-year undergraduate degree program with the addition of a substantial component of nonspecialized or general education. The introduction of the new academic structure with the one-year expansion of higher education leads university administrators, teachers and scholars to explore the reinvention of undergraduate education in Hong Kong [3]. This reinvention is not limited to the curricular redevelopment. In fact, holistic development, including the expansion of different learning experiences such as out-of-classroom learning experiences and service-learning opportunities, is emphasized as well. The University Grants Committee [7] asserted in their official webpage that having an additional undergraduate year will "enable students to have more time and space to build a broader knowledge base and a more solid foundation for whole-person development" (paragraph 2).

This openness challenges the long-held belief of “academic excellence surpasses other things” initiates the establishment of general education in Hong Kong [8].

The advocacy of general education in the higher education setting echoes with the emphasis on students’ “lifelong learning” and “all-round development” in the education reforms [8]. In addition, the establishment of general education in higher education setting strikes a right balance between the breadth and depth of different programs and help students “develop a sense of integrity, positive attitude, a broad vision and important generic skills” [9]. Most importantly, general education could provide the freshmen opportunity to map out their own study paths to suit their interests and aspirations. This flexible and student-centered education helps nurture students’ whole-person development, enrich their undergraduate learning experience and foster their well-being in general.

Echoing the comprehensive curriculum reform carrying out in higher education in Hong Kong, the eight public higher education institutions in Hong Kong have all extended their undergraduate degree program from three years to four years, mandated by the University Grants Committee (UGC) since the 2012-13 academic year. With this implementation, each institution developed its new four-year curriculum by adding a significant general education component. Among these universities, one remarkable case was The Hong Kong Polytechnic University (PolyU). Since 2012-2013, PolyU implemented a new general education curriculum, named “general university requirements” (GUR) as an integral and significant part of its new four-year undergraduate degree program. The objective of GUR is, in combination with students’ specialized education, to provide an all-round education to all PolyU students, with a particular focus on nurturing them on five desired graduate attributes, including effective communication, critical thinking, problem-solving, lifelong learning and ethical leadership. The nurturance of these attributes is facilitated by different GUR requirements including leadership and intrapersonal development requirement, cluster area requirements, freshman seminar, service-learning requirement, language and Communication requirements, and healthy lifestyle.

To evaluate the effectiveness of the GUR, a five-year longitudinal evaluation project has been conducted since the inception of the new 4-year undergraduate curriculum in the academic year 2012-2013. Different quantitative and qualitative evaluative components have been carried out in evaluating the implementation and effectiveness of the GUR. One of the examples is the longitudinal study with 4 waves of data to investigate how the university students grow with the assistance of the GUR in the researched university [10]. The study has revealed significant changes in most well-being indicators over time.

Although quantitative studies are helpful, they may not capture the inner experiences of the students. The present study is one of the qualitative evaluation studies of the project. This study attempted to investigate the effects of general education on student development in the Hong Kong context. It helps to broaden readers’ understanding of the association between general education and freshmen development, and factors contributing to this association. A longitudinal case study was adopted as one of the evaluative methods in the present project. Case study is one of the most common research methodologies employed in educational research [11, 12]. Most of the scholars reached the consensus that a “case” should be the phenomena happening in the “bounded system” where researcher’s concern, interests and hypotheses might rest upon [12]. With such bounded systems, researcher aims to “uncover the interaction of significant factors characteristic of the phenomenon” [13]. “Case study” is specifically appropriate for the present study where the researchers attempted to study a

single case (The Hong Kong Polytechnic University) and the newly implemented general education curriculum named “GUR requirements”. In addition, how freshmen perceive the assistance of GUR in their transitional stage from secondary schooling to the university life is what Shaw [14, p.2] suggested that researchers should focus on “particular groups of people confront[ing] specific problems”. Although the researchers are from the researched university, the employment of case study allows the researchers to examine the relationship between “what was known” and “what previous unknown” and leads to a “rethinking of the phenomenon” [15]. Concrete and contextual insights could be drawn from this case study with researchers’ resonations with their own experiences rooted in the researched university.

Regarding utilizing case study as an evaluation method in research, Guba and Lincoln [16] have concluded that case study is the best reporting form for evaluations. Case study can at its best in providing thick and grounded description and is “holistic and lifelike” [17]. The case study not only allows the researchers to revisit the contexts they have been situating, but also enables readers to bring in their own experiences and understanding which lead to “generalization when new data for the case are added to old data” to thicken the description of the understanding [15]. As the participants are freshmen of the researched university, the students can add on their own experiences while the researchers were conducting the interviews. This addition has facilitated researchers to investigate the differences of views and suggest how these influences have influenced the understanding and perception of the assistance of GUR.

In the present study, a group of students (“cases”) were followed up by researchers on their personal growth starting from the freshman to graduation year. This would help trace the changes and development of individual students throughout their university lives and further understand students’ voiced views on their GUR study in greater details. The present study denotes some of the general observations based on researchers’ first-year following up with the freshmen.

OUR STUDY

Purposive sampling was adopted in the case selections. A total of 71 cases from different faculties or schools were recruited from participants of student focus groups held in the academic year of 2012-2013. The students shared their general impressions on their first-semester experience of taking some of the GUR subjects in the focused group interview. These students were invited to participate in the present study of having the longitudinal case study in the form of in-depth interviews. In the present study, the authors report the findings of the second-year longitudinal case study. After the initial contacts in the first year (71 cases), 42 actively engaged cases (59.2%) who maintained regular contacts with the researchers and 10 re-activated cases who had one or two meetings with the researchers during the past year. The remaining 19 student cases (26.8%) showed no interests in joining the study and did not respond to the several rounds of invitations by the researchers. These cases have now been deleted from the longitudinal study. At the beginning and the end of the 2013-2014 academic year, researchers conducted individual interviews for those 42 actively engaged cases using an interview guide developed by the research team. In addition to the two individual interviews each year, informal meetings with the student participants were

held by the researchers in each semester. Students were invited to share their university experiences, challenges encountered, and personal gains during the semester with the researchers in a more relaxing milieu.

Regarding the recruitment of researchers, eight researchers from the Department of Applied Social Sciences of the researched university started to follow the student cases commencing on the 2013-14 academic year. Most of the researchers had experience in teaching the GUR subjects. This shared experience constituted the common language between the researchers and the students. This “common language” assists the researchers to better understand students’ sharing during the interviews and such an empathic understanding will hence foster the students’ trust in sharing their own experiences in the interviews reciprocally. The trusting relationship between the students and researchers reinforces the process of thickening the data [11]. Each researcher was responsible for seven to eight cases. The constant encounters between the researcher and students assist the researchers to better capture the deep meaning of experiences in students’ own words in the form of individual in-depth interviews [18]. The researchers act as the “miners” and “travelers” in the interviewing process to unearth the meanings initiated by the students and wander together with the students to “the unknown terrain” and co-construct the “new knowledge” with more interactive involvements in the interviewing process [19, p. 48]. With the mining and traveling between the researchers and students, the substance of the interchanges is constructed and thus the meaning-making process could be thickened.

Instrument

A semi-structured interview guide developed by the authors was adopted in the study to explore students’ views and experiences about the GUR and their university study in general. The interview guide comprised two major categories: students’ experiences in GUR in relation to personal growth and the development of five graduate attributes of PolyU (including critical thinker; effective communicator; life-long learner; problem-solver and ethical leader), and students’ perceptions and expectations of their university lives. The inclusion of students from different faculties and schools was intended to gauge students’ perceptions on GUR with reference to their professional disciplinary training. This arrangement could help facilitate the students to have some “debates” between their established internal frame of reference upon disciplinary professionalism and their perceptions on the GUR. These debates could further facilitate the establishment of a “framework for discussion” in relating their experiences in learning the GUR during the interviews [11].

The researchers were allowed to change the sequence or wording of these questions during their interview process. The questions in the interview guide were listed as below:

1. Apart from the knowledge in your major (disciplinary specific study), what do you think an undergraduate student should learn in his/her undergraduate years? What qualities should a university student develop during their undergraduate study?
2. Do you know the five desirable attributes (critical thinking, effective communication, innovative problem solving, lifelong learning, and ethical leadership) of a PolyU

graduate? What is your understanding of these attributes (e.g., perceptions and importance)?

3. Do you feel that you have grown or become more mature in terms of the desirable attributes in the past semester/academic year? If yes, please let us know more about the experiences?
4. In retrospect, do you think the GUR subjects have helped you to develop the ideal PolyU attributes? Have you applied what you have learned in GUR subjects in your life?
5. Do you have any plans/goals for the rest of your university life? How may any GUR subjects or other resources the university provides help you achieve your goals?

The audio recordings of all the interviews were fully transcribed into texts. The method of thematic analysis was used to analyze and code the data to better understand the complexity and richness of the case. Two part-time research assistants with Master degrees and one postgraduate student pursuing a Master degree coded different parts of the data into different themes under the careful instructions and supervisions of the authors. During the coding process, the authors met with all coders twice to provide feedbacks on the coders' partial coding work. After the coding, all the codes were combined together.

Based on the interviews, each interviewer was invited to write a one-page summary based on their observations during the interviews and the informal meetings with students. These summaries are served as "complementary sources" to understand the researchers' views on their comprehension of students' sharing in the interviews. The use of researchers' summaries helps gauge the "factors normally hidden" and "idiosyncratic variables" that interviews might not reach [20]. The "hidden" elements revealed in the researchers' summaries could help thicken the interpretations of data obtained in the interviews. The summaries were read through and analyzed by researchers from the research team.

DISCUSSION

Several general observations were derived from the researchers' summaries on student development and their views towards GUR study based on the transcriptions. First, most researchers mentioned that they have developed trusting and reciprocal relationships with their case students which were beneficial to students' self-disclosure of their views on GUR study and university life. Second, three major observations on students' views about the effectiveness of GUR study were generated. These included 1) broadened horizons, 2) increased awareness of the connection between GUR study and all-round development, and 3) urge for linking GUR Components with one's profession.

Trusting and Reciprocal Relationships

Researchers have agreed that trusting and reciprocal relationships had been established through the constant encounters or informal meetings with the students. It is believed that the relationship helps college students better adapt to the life as a freshman, and most

importantly, the researchers' understanding and self-disclosure in the process support its beneficial role on students' learning outcomes [21]. One of the researchers stated the impact of empathic understanding and self-disclosure on her student case in her summary:

From the interviews, I witnessed the personal growth of my students after taking these experiential and diversified courses. I felt their enthusiasm and excitement on learning. Meanwhile, a closeness relationship was established between us. When listening to their sharing and thoughts (e.g., memorable service learning experience, academic study difficulties and personal issues), I also shared my thoughts and feelings with them (e.g., difficulties and challenges that I faced in my freshman years of college).

College students' level of strain was generally highest during Semester 1 in their freshman year. This period is predominately an anxiety-provoking time for college students [2]. Although the researchers approached a limited number of students compared to the entire student population, the timely support and empathic understanding from the researchers led students to their awareness of "personal growth" and helped lighten their anxiety in their first year of study in the university. In addition, this connection between the researchers and the students fostered human spirituality. Spirituality has been demonstrated to be uniquely and meaningfully associated with university students' psychological health [1].

Broadened Horizons

Students acknowledged that GUR subjects provided them with opportunities to understand knowledge beyond their own disciplines. Quite a number of researchers reported that the students were exposed to domains that "they have never seen" or "they seldom have experienced before". Learning experiences in GUR study also promoted students' "openness" to new things and challenged their preoccupations. For example, while some students initially perceived GUR subjects as simply "mandatory" to fulfill for graduation or "not as useful as the major subjects", these misunderstandings and preoccupations were quashed after the students had immersed themselves in learning these subjects. Students in different interviews noted that they were "more aware of the importance of service and learning" after taking the SL subjects; they also understood that "leadership actually relates to personal qualities and individual development" after studying LIPD subjects.

For the course "Tomorrow's Leaders", it is not about how to lead others but leading oneself, that is "self-leadership". That is why we have to behave well and be the role-model of others.

I am a passive person and usually listen to others' commands. I am not an in-born leader. I love to be in the supporting role...this is my personality and I might not be that brave to be the leader.... But I would like to learn more about the concepts and skills in the course to see if I could try later in my life.

Most students also reported that CAR subjects "exposed them to a new world". These experiences encouraged students to view things from different perspectives and be aware of one's preoccupations. From the researchers' reports, students have developed a more reflective attitude toward their lives through multiple reflective activities in GUR classes (e.g., LIPD subjects like "Tomorrow's Leaders" and SL subjects). Similar point of views is found in students' interviews.

When a decision is made, I will think of the reasons of making that decision and its applicability on the problems. When I am willing to reflect upon what has happened, I have learnt a lot from a newer perspective.

I will always ask myself “why did I fail this time?” and the disappointment generated will be lingered on for a while. But I think time is usually too short for happiness. Sufferings make one grow. I will reflect upon the sufferings and think of ways to improve.

Students’ responses also assured the importance of experiential learning adopted in most GUR subjects. The focus of the experiential learning is not just the experience itself but the reflections on the experiences which are instrumental to personal growth. The interview process has granted students’ opportunities to reflect upon their first-year learning experiences as well. Some students have expressed their appreciations for the researchers to have offered them a chance to “talk over” and “explore” their ways of thinking and understanding of their new academic lives, with the assistance of the general education GUR in the university setting.

Increased Awareness of Connection between GUR Study and All-Round Development

Students’ awareness of the importance of GUR study in helping their personal development has increased. Researchers learned from the cases that students enjoyed the interactive and collaborative learning activities conducted in most GUR subjects and perceived such teaching and learning methods to have helped them step out of their comfort zone and polish their social and interpersonal skills. The strengthening of students’ sense of connectedness and thus their optimism has enhanced students’ well-being and “feelings of relief, happiness, perceived social support, and [thus] quality of life” [1]. Other skills such as critical thinking, problem-solving, and leadership were also taught and practiced in GUR study, which echoed the desirable graduate attributes defined by PolyU. Students believed that these skills were indispensable for their all-round development thus enabling them to become competent professionals in the future.

Usually most of us would only encounter friends from our own discipline. Certainly, knowing friends from our own discipline will help me build a future network and gain some help for the professional examination. But we should extend our social circle. Studying GUR could help extend my social circle and have my social network extended.

We should know more than our own disciplinary knowledge. We should learn knowledge from other disciplines. And the learning should not be limited to the “present moment”. It is life-long learning that we could learn after graduation.

On the other hand, researchers reported that several students knew less of how the “desired graduate attributes” of PolyU could be developed through the general education course, although these attributes were yet subtly and progressively developed through their learning experiences. This indicates that more efforts are warranted to help students know more explicitly what the expectations of the University are and the importance of holistic development in terms of how these expectations relate to one’s professional and personal growth.

Urge for Linking GUR Components with One's Profession

Researchers reported that although the students in the present study agreed that the GUR components have provided them with new learning experiences, they were not able to clearly identify the linkage of different GUR components with their disciplines and profession. The aim of providing general education in higher education settings is to offer students another platform for exploring and developing students' various competencies and skills, and to have "major transformation of both faculty and student orientations toward the learning process" [22]. PolyU has her own strong tradition in making knowledge into practice and it is understandable for the students' urge for linking up what they have learned in the University to their professions. Judging from the students' responses, there seems to be a gap between University's rationale for general education and students' understanding of the aim of general education.

At first, what I understand of GUR is to choose [the subjects] we like or are interested in. This is to equip ourselves with different talents and thus to develop ourselves. But it seems that not every university student understands the importance of GUR. I think this is a problem. The design of the GUR is nice and helpful for our growth. It is sad to know that we do not understand its rationale well.

The students were aware of the "problem" of not understanding the rationale of the general education offered. They felt "sad" about not being able to understand how the general education assists their personal discovery and growth in their freshman year. With such gap and insufficient understanding of the purpose of general education, such "urge" might hinder students' integration of their learning experience with their personal growth. While it takes time for students to understand the meaning and importance of general education to their professional development, more opportunities for reflecting upon the purposes and meaning of learning the GUR components should be given to students during their learning experiences in the GUR. Even though the case students may have accomplished their freshman year, they are still experiencing the initial stage of university life. With maturity in their professional and personal growth to be expected in later years, the relevance of what they have learned in their disciplines and the GUR components to their own life development may be gradually seen.

There are several strengths of utilizing case study as the major research methodology in the present study. First, the focus on freshmen perspective could assist the researchers to focus on freshmen's perceptions upon how the GUR could have been maximized in the fixed period of time available in case study [23]. Second, the present study gave the students an avenue to share their perceptions and understanding of the general education implemented in the researched university. This inclusion is a "highly significant part of the story" [24] that has facilitated the exploration of the meanings of GUR in freshmen perspective and thus thickened the understanding. Third, case study is known as a triangulated research strategy [12, 25]. The present study is one of the evaluative components of the longitudinal research project. The findings of the present study could be used to ensure accuracy and alternative explanations of other evaluative components in the project.

Despite the strengths of the present study, some limitations are noteworthy as well. First, the cost-effectiveness of collecting and analyzing the data is doubted. Scholars have commented that both the data collection and analyses pertaining to case study are time-

consuming [12, 25]. Second, the data collected in the present study may not be generalizable in the conventional sense. The sample in the present study focuses on the freshmen of a single university that the sample may be idiosyncratic. It would be difficult to establish the likelihood that the data are representative of some larger population of other universities in the Hong Kong context [24].

Overall speaking, researchers' reports and students' interviews on the first year longitudinal case study suggest that students generally had fruitful learning experiences in GUR study. While students became more aware of the benefits of GUR study, the linkage between different GUR components and students' professional development could be further highlighted. Longitudinal follow-up studies would help to form a clearer picture of students' views toward GUR and their personal development.

ABSTRACT

Using a longitudinal case study approach, this study investigated students' development in their undergraduate years and perceptions of the "General University Requirements" (GUR) in the new four-year undergraduate curriculum of The Hong Kong Polytechnic University (PolyU). Forty-two students enrolled in the new curriculum were invited to participate in yearly interviews, with 42, 31, 20, 23 students finally completed the yearly interviews from Year 1 to Year 4, respectively. Students' views in different academic years systematically indicated that the GUR program helped to promote

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

students' development in a holistic manner, particularly with reference to the development of PolyU desired graduate attributes, knowledge broadening, and mental health promotion. Students' views towards different GUR subjects and the overall university education were also positive. Meanwhile, some challenges mentioned by students were noted for further improvement.

INTRODUCTION

General education, once an important legacy of American higher education, is now being widely adopted in higher education institutions all over the world [1]. A recent report showed that at least 58 countries have included in their higher education curricula some general education elements, of which Asian countries constituted a major part [1]. There are both factors outside and inside the university for the growing adoption of general education ideas and programs. With regard to factors outside the university, the rapid economic and workplace changes and the fast obsolescence changed the nature of work and study. Many university graduates may need to change their jobs several times over their entire career life [2]; more and more working people return to university for a second major or retraining; and many university students might not do jobs relating to their original specialized field of studies in university [3]. The fast-changing, increasingly interconnected, and globally competitive world also reshaped the manpower requirements of workforce.

Beyond professional knowledge, employers expect their employees to have strong transferable skills, critical thinking, effective communication, innovative problem-solving skills, as well as a sense of ethics and responsibility to not only adapt to the fast-changing environments but also help with enhancing the international competitiveness of the nation [2, 4-6]. A report of Association of American Colleges & Universities (AAC&U) [7] claimed that more than 70% of employers expected university education to put more emphasis on developing generic competences such as teamwork skills, oral and written communication, critical thinking, analytic reasoning, innovative problem-solving and global awareness. Therefore, a narrow undergraduate education is unable to equip students with these required competences for a changing world. David Kearns, the former CEO of the Xerox Corporation said:

"The only education that prepares us for change is a liberal education. In periods of change, narrow specialization condemns us to inflexibility-precisely what we do not need. We need the flexible intellectual tools to be problem solvers, to be able to continue learning over time." [8, p. 2]

For the need within the university, the changing profiles of current university students and their increasing psychological and behavioral problems also raised concerns of university administrators, teachers, and scholars. Research consistently showed that there was an increasing high prevalence of mental health problems among university students [9, 10]. Challenged by a double transition from adolescence to adulthood and from high school to university stage, university students were much vulnerable to mental health problems [11]. Some common mental health problems included depression, anxiety, and stress [11, 12]. Also, university students reported higher levels of emotional problems, suicidal ideation, and psychotic disorders compared with their normal generation [11]. Therefore, both the outside challenges and inside needs suggest that more strong educational initiatives or interventions

should be provided to university students to help them adapt to critical transition and develop better to thrive to be competitive professionals and citizens in society. General education, with its outmost aim as developing holistic person, is an important mean to help university fulfill this task. This is as claimed by Louis [13, p. 31] that “general education has been perceived as a medicine to cure many ills, including overspecialization and vocationalism, to incite much virtue in areas as civic responsibility, and to prepare individuals for full self-realization.” Also, the value and meaning of a general/liberal education in contemporary age was claimed by AAC&U [7] as:

“Liberal education is an approach to learning that empowers individuals and prepares them to deal with complexity, diversity, and change. It provides students with broad knowledge of the wider world (e.g., science, culture, and society) as well as in-depth study in a specific area of interest. A liberal education helps students develop a sense of social responsibility, as well as strong and transferable intellectual and practical skills such as communication, analytical and problem-solving skills, and a demonstrated ability to apply knowledge and skills in real-world settings.”

Propelled by the above-mentioned internal and external factors, there have been movements in different places of the world to enhance general education component or introduce new general education programs in undergraduate curriculum of higher education. Meanwhile, the emphasis of general education implementation has changed from focusing on its curricular content to innovative and engaging teaching and learning approaches that promote “modes of learning that are collaborative, experiential, service, and integrative” [14]. Based on this shifted conception, different innovative and engaging curricular modes and pedagogy were developed, which included freshman-year seminars, learning communities, service learning, collaborative assignments, capstone courses, and writing-intensive courses, and other engaging courses [14, 15]. The underlying rationale of these new initiatives, as claimed by Schneider [15, p. 34], reflected a philosophy of general education that:

“It emphasizes an approach to learning rather than course categories, and gives primary attention to the habits of mind, breadth of perspective, and capabilities the student is developing. The ability of students to apply their knowledge to real problems is one indicator of their achievement level.”

In line with the worldwide trends, there was a new general education initiative in higher education in Hong Kong in recent years. Since the 2012-2013 academic year, the eight public universities in Hong Kong extended their three-year early-specialization-oriented undergraduate degree programs to a four-year length. In the new four-year curricular structure, a significant general education component was introduced. This curricular transformation is a systematic response of Hong Kong higher education to the ongoing social and economic changes of Hong Kong society in an increasingly globalized age [16, 17]. Among different new general education programs, a notable one was the “General University Requirements” (GUR) developed and implemented in the new four-year undergraduate degree program at The Hong Kong Polytechnic University (PolyU). In addition to arming students with a broad knowledge base and learning experience, the GUR at PolyU is also intended to nurture PolyU students in five desired graduate attributes, including effective communication, critical thinking, innovative problem solving, lifelong learning and ethical leadership. To achieve these goals, the GUR is comprised of six major learning components, including Freshman Seminar, Leadership and Intra-Personal Development Component, Language and Communication Requirements, Cluster Area Requirement, Service Learning,

and Healthy Lifestyle program. Across these different components, the GUR framework adopted new pedagogies such as hands-on workshop, service learning, group projects, writing assignments, in-class activities and other approaches to engage students in a more in-depth, collaborative and experiential-based learning. The objectives and characteristics of each GUR component are briefly introduced below:

- Freshman Seminar (FS): a three-credit subject in each broad discipline designed to broaden students' understanding of their chosen discipline and nurture their entrepreneurship and university-preferred learning styles.
- Leadership and Intra-Personal Development (LIPD): includes two alternative leadership subjects: "Tomorrow's leaders" and "Tango! Managing self and leading others" to nurture students' knowledge and skills pertaining to successful and ethical leadership.
- Language and Communication Requirements (LCR): includes both English and Chinese subjects to develop students' oral and written language proficiencies in English and Chinese.
- Cluster Area Requirement (CAR): to choose four subjects respectively from four cluster areas to expand students' intellectual capacity and develop their reading and writing skills as well as an understanding of China.
- Service Learning (SL): subjects with significant service components where students need to take one to apply academic knowledge in practice and develop civic responsibility.
- Healthy Lifestyle (HLS): includes a series of learning including online tutorial and sports-doing classes to help students establish healthy lifestyle.

While the program of GUR was carefully designed and innovative teaching and learning methods were incorporated, how well this program works and how effective it promotes students' all-round development were less studied. In view of this, a five-year longitudinal evaluation project with multiple evaluative approaches has been conducted since the 2012-2013 academic year. The project was intended to understand the effectiveness of the GUR in promoting students' all-round development, particularly their development in the five desired graduate attributes of PolyU. The project was comprised of five major evaluative components: (a) longitudinal online survey; (b) Collegiate Learning Assessment Plus (CLA+); (c) secondary analyses of Student Feedback Questionnaire data; (d) student and teacher focus groups and written qualitative evaluation; and (e) longitudinal case study. For the first four components, they have generated rich and solid results. For example, the longitudinal online survey and CLA+ found that students had better performances in a set of developmental indicators in their junior and senior years than in their freshman and sophomore years [18, 19] and PolyU students performed better than did control group students [20, 21]. Student and teacher focus group results indicated that in different years, both students and teachers perceived that different GUR subjects helped with their holistic development in different aspects [22-24].

However, there is still a need to conduct longitudinal individual case studies. Different from focus groups based on different students in different years, longitudinal case study follows the same group of students over the four academic years. Thus, students'

development over time could be more systematically identified. Also, longitudinal case study was based on individual interviews, which could help probe individual students' perceptions in deeper and richer approach. Moreover, data from longitudinal case study could help further triangulate with or interpret data from the objective outcome evaluation such as longitudinal online survey and CLA+ and other qualitative evaluation such as focus groups. Against the above background, this paper reports the methods and findings generated from the longitudinal case study component of the GUR evaluation project. It helped to answer the research question that how students perceived the GUR and how they develop under the GUR program over the four academic years.

OUR STUDY

In the 2012-2013 academic year, 71 first-year students enrolled in the four-year program of PolyU were recruited based on purposeful sampling. These students were invited to participate in a longitudinal case study in the GUR evaluation project. They had been followed up by a group of scholars about their development and perceptions of the GUR over their four-year study since the 2012-2013 academic year. In each academic year, each student would be invited to attend an individual interview conducted by their respective scholars. Since during the 2012-2013 academic year, only 42 students performed actively in the study and the other 29 students acted inactively, the 29 inactive students were removed from the study. The 42 active participants were further invited to participate in the yearly interviews in the following three academic years (from 2013-2014 to 2015-2016). The number of students who finally attended the interviews in each academic year was 31 for 2013-2014, 20 for 2014-2015, and 23 for 2015-2016. All interviews were conducted around the end of the different academic years, with a length from 0.5 to 2 hours. All interviews were audio recorded. After each interview, the student was given a supermarket coupon as an incentive.

An interview guide with a set of semi-structured questions was developed by the authors to guide the individual interviews of the study in each academic year. The questions focused on (a) students' perceptions of different GUR subjects, (b) their personal growth during each academic year and previous years, (c) the contribution of GUR to their personal development, and (d) students' overall views of their four-year university study.

After the interviews of each academic year, all audio records of individual interviews were transcribed into full transcripts with the help of a group of trained student helpers. Then these transcripts were divided into three parts to be given to three trained research assistants for coding. These research assistants coded these transcripts based on method of thematic analyses and generated themes under supervision of a senior researcher who had solid experiences in qualitative study and data analyses. In the middle and at the end of the coding work, meetings were held and different research assistants' coding work was compared with each other and cross-checked, based on which relevant revisions were made to keep consistency of the coding. After the fourth-year data collection and coding work, a senior researcher combined the codes of all four years together and generated a comprehensive coding scheme of the study.

FINDINGS

The data collected over four years revealed that students generally had positive perceptions of the GUR program, particularly with reference to its subject content, teaching and learning methods, and quality of teachers. Students generally perceived the contents of different GUR subjects as useful, attractive and important. They commended highly the engaging pedagogies adopted in different subjects and the high quality of subject teachers. These views of students were presented in detail as below.

Attractive and Useful contents

One theme emerging from students' four-year narratives was students' positive views of the contents of different GUR subjects. Students generally perceived the GUR subject contents as rich, attractive, important and useful. For example, some students perceived the content and knowledge covered in the "Tomorrow's Leaders" subject as very important to their development. They said: "it ('Tomorrow's Leaders' subject) taught you something useful and let you know that to be a leader you need to have a lot of different abilities. This is very important." Students also appreciated that the freshman seminar subjects provided them opportunities to understand different professions in their broad disciplines and their interconnections. Furthermore, students commented that CAR subject contents were "very interesting" and "very rich" and fulfilled their desire to study their interested subjects beyond their own majors. In one interview, one student expressed that "the CAR subjects let us study based on our own interests" and "we have never expected that the University could offer these subjects to us such as the subject on 'logics and reasoning'." More narratives were provided below to illustrate students' views.

"I found this (CAR) subject very interesting. It conveyed to us something about human nature, some social phenomenon and some other issues that science fiction films would like to convey to the public."

"I have strong interests in Chinese culture and China. Therefore, I want to learn more through this (CAR) subject. Meanwhile, I am also interested in religion. This subject just taught the Buddhism and Chinese culture. It taught us different religions in Chinese culture and their influences to ancient, modern and contemporary Chinese societies."

EXPERIENTIAL AND INTERACTIVE LEARNING AND QUALITY TEACHING

Over the four academic years, students also had general positive perceptions of the teaching and learning in different GUR subjects. This was manifested in different aspects. Commonly shared by students, one major characteristic of the GUR was its "experiential learning" components incorporated in many different subjects, which included hands-on workshop in Freshman Seminar subjects, fieldwork in CAR subjects, and service project in Service Learning subjects. These "experiential learning" components gave students a vastly different learning experiences that cannot be gained through traditional subjects, which greatly engaged students in learning and was highly welcomed by students. Besides, lots of

students favorably commented on Tomorrow's Leaders' (one leadership subject) for its delicately and carefully designed in-class activities and in-class games to facilitate students' learning and apprehension of leadership concepts. Some games were icebreaking games to help students get familiar with their group members. Some games were classical leadership-promotion games to help students practice leadership skills such as teamwork or cooperation. Students viewed these activities and games very positively, perceiving these activities as helpful not only to their understanding of leadership concepts but also to creating an active and relaxing class atmosphere to engage and facilitate their learning. Students' positive views of different innovative and engaging pedagogies were illustrated by narratives below.

"I liked the Solar-Car-Making project (in Freshman Seminar subject)! I had never done this kind of hands-on projects in my high school. In this project, we needed to complete all the design work by ourselves and the subject teacher only provided us raw materials. This is really good and fun because we really 'made' something out. The sense of achievements from this project was much greater than that from studying textbooks."

"There were many interactive elements in the 'Tomorrow's Leaders' subject, or many so called 'small games'. We might not know our groupmates at the very beginning of the course. But we got to know each other better and united our team members quickly through playing these games. Meanwhile, we could comprehend something behind each small in-class game."

"I remembered in one class (of 'Tomorrow's Leaders' subject) we did an activity to draw superman figures. We put a lot of efforts to draw and then presented to others how our drawing illustrated the advantages and disadvantages of teamwork. Our group was very united in doing this and felt very happy."

Students in different years also commented positively on the good teaching skills of some teachers, particularly the CAR subject teachers and teachers in "Tomorrow's Leaders" subject. Students perceived some teachers could teach "beyond the content of PPT" and could use methods such as "story telling" or "case sharing" to illustrate the content of lectures. This can be illustrated by the following two narratives.

"She gave us a lot of examples. Also, in every class, she did not just teach new knowledge but helped us review the previous knowledge. For example, she would remind us of the linkage between topics in current lecture and the previous lectures, which made us know that different topics were not isolated."

"This topic ('Spirituality' in Tomorrow's Leaders subject) is difficult. Nevertheless, in our lectures, Amy (alias of the subject teacher) worked very hard to explain this concept to us. Then when we are doing our group projects, Amy and Alice (alias of the tutor) provided a lot of support to us, which helped us to understand this concept."

Students' Development under the GUR

Multiple aspects of development and benefits were perceived by the students who have studied the GUR subjects across the four academic years. These developments and benefits included a broadened knowledge base and horizon, effective communication, effective and ethical leadership, critical thinking and innovative problem-solving skills, as well as other positive developments. Students also indicated their capability of applying certain knowledge and skills into practice. These different aspects of development were presented in detail as below.

BROADENED KNOWLEDGE BASE AND HORIZON

One important benefit of the GUR was that it helped to broaden students' knowledge base and horizons. Students over the four years consistently perceived this benefit. Meanwhile, along with progression of university study, students increasingly realized the importance of having a broad knowledge base and horizon to their future development. Students found that Freshman Seminar subjects shaped their understanding of knowledge in different specialized fields of studies covered by a broad discipline and helped them meet students from different disciplines. Students perceived in different years that CAR subjects broadened their horizons as they had met students from different disciplines and even from different academic years. Students benefited a lot from communicating with these different peers. Besides, across different years, students shared that service learning subjects also helped broaden their horizons. These subjects, particularly for those offering overseas service experiences, provided students with opportunities to experience and learn different cultures and people living in different conditions. Through these experiences, students' horizons were broadened and their understanding of society was enriched. Students' positive views of these benefits can be illustrated by narratives below.

"If there have been no these subjects, we might have developed to be narrow professionals. But we have had these subjects. They could stimulate our multi-perspective thinking and let us try different things. For example, in Healthy Lifestyle program, besides badminton, I also took a hip-hop course. Although I like hip-hop very much, I had no opportunity to study it before. But the University provided me this opportunity and I would like to have a try. This really could broaden our horizons."

"These (CAR) subjects are very useful to facilitate our interpersonal communication and broaden our horizons. You see, we could study Psychology, Biology, or Map Reading. These subjects could help broaden our knowledge base beyond the engineering field (the student's major)."

"To see society and culture of a different place will broaden our horizon largely. Before my service learning trip, I only focused on what happened in Hong Kong and only knew that Cambodia was an underdeveloped country from the TV. But this understanding was very shallow. When I finished my Cambodia project and experienced life there, I was deeply shocked and felt that 'actually there are so many people in the world who are less fortunate than me!' The experience made me to do a lot of reflections."

Effective Communication

Communication competency was another major aspect of development of students through studying GUR subjects. Two approaches contributed to students' effective communication. First, students' effective communication was promoted by English and Chinese Language and Communication subjects offered in different years. These subjects enhanced students' writing skills through specifically teaching these skills and practical writing practices in assignments. Some students reflected that they could apply these learned writing skills to the writing assignments in their major subjects. Besides, students reported that these Language and Communication subjects trained their different oral communication skills, such as discussion skills, class-presentation skills, and interview-presentation skills. This was through different innovative and engaging teaching methods such as group discussion tasks, in-class presentation and role-play activities. The benefits of language and communication subjects to students' effective communication were illustrated by two narratives below.

“These subjects (English and Chinese) included mock interview parts. Therefore, they trained our expression skills in job interview. Meanwhile, they taught us how to write letters, which is very useful.”

“My year one study built a good foundation for me. I find very interesting because at the very beginning of my study, the English subjects taught me how to find materials and how to write an essay. These helped with my major subjects because we had a lot of writing tasks in our major subjects.”

Across different academic years, students’ effective communication skills were also enhanced through engaging in different interactive learning activities in different GUR subjects such as attending different group-based learning activities and performing different writing assignments. For example, some students claimed that the hands-on group project work incorporated in most Freshman Seminar subjects trained their skills of discussion and negotiation through group members working together to make out one product. Students also commented that “Tomorrow’s Leaders” subject trained their presentation skills through class teaching and in-class group presentation tasks. Moreover, students’ effective communication was also promoted by Service Learning subjects that provided students opportunities to work ingroup to design and implement a service project. This kind of group work facilitated intensive and in-depth communication between group members and large amount of communication between students and service clients. During the group work process, lots of students perceived an improvement of their skills to communicate ideas in groups and with people outside of the campus. For example, students expressed below:

“Students needed to communicate with others (in the service project) no matter what majors they came from. When going to a place, no matter in a local or non-local service project, we need to communicate with others. When doing some activities, some students who were not good at communicating with others were pushed to communicate. To have opportunities to practice our communication skills is a good thing.”

“In Year 1, I am not good at communication. I was very stubborn in communicating with others and would stick to what I think is right. I also communicated with others in this way in my Service Learning subject. Although I only wanted to speak out my own thoughts, the others thought I was objecting to their views. Therefore, I tried to improve my ways of communication from then on, and tried to be softer in communication with others.”

Effective and Ethical Leadership

Students’ leadership awareness has demonstrated an increase along with their four-year university study. For example, in the third and fourth years, more students perceived the leadership development as important to their personal and future development. For example, one student clearly claimed in the third-year interview that one of his future goals was to “strengthen leadership and learn how to become an ethical leader.”, while he did not demonstrate this idea in the first and second year interviews. Students’ leadership attributes have been nurtured by different GUR subjects in different years. Firstly, the “Tomorrow’s Leaders” subject provided an important platform for students to learn and understand leadership knowledge and concepts. Students in interviews in different years all expressed that the subject was useful, which enhanced their understanding of the quality of a good leader, improved their self-understanding and understanding of “self-leadership”, helped them to reflect on their leadership skills in practice. For example, one student said “I always remember what Iris (alias of the subject teacher) said that we not only need to lead others but also need to lead ourselves. So, ‘Tomorrow’s Leaders’ subject really helped us in leadership development.” In another example, a student talked about his understanding of the concept of

“spirituality” and its impact on his personal life. The student said “based on my understanding, spirituality means we should have a firm belief” and “based on this, I began to feel that I should not waste time in the four-year university period and I should have faith to study hard on my own major.” Furthermore, a student talked about how he applied the leadership knowledge learned from the “Tomorrow’s Leaders” subject in his leadership practices:

“One lecture (of ‘Tomorrow’s Leaders’ subject) taught us different leadership styles, such as the difference between the leader ordering his subordinates to do things and the leader joining in the teamwork and leading and instructing his team members to do something. I prefer the latter one. For example, when I was in charge of some activities, I normally joined to work together with the whole team and then told my team members how they should do about the task. Under these circumstances, I feel that I am applying leadership theories learned in practice.”

Besides the “Tomorrow’s Leaders” subject, across the four years, students also gained a lot of different chances to practice leadership skills through different group project work experiences in different GUR subjects, such as freshman seminar and service learning subjects. Particularly, through group projects in service learning subjects, students learned how to collaborate with other students from different departments and how to collaborate with different people outside of the University to perform better services to the community.

“Service Learning helped my leadership development. When my group was to do a service, I had chances to take the leadership role to lead our group to accomplish the service project. I also learned how to get along with people and how to communicate with groupmates about the project.”

Social and civic responsibility was important component in students’ development of ethical leadership. Students generally perceived that Service Learning subjects nurtured their social responsibility and civic awareness. For example, through helping underprivileged people in different places in their service learning projects, some students developed a strong sense of social responsibility to help underprivileged people in future and also reflected on their life values. Service Learning subjects also helped some students understand the social roles of their professions and helped them review their intentions in studying their professions. This influence was profound and even lasted to students’ senior-year period. For example, two students shared the influence of service learning experiences to their social responsibilities in their senior-year interviews, respectively:

“I think the most important thing is the (Service Learning) subject changed my attitude toward my profession. It made me remember why I choose to study physiotherapy in university. The major reason is that when I was very young, I have seen some doctors in *Doctors Without Borders*. They are so good and so great. So I also hope that I could use my profession to help others.”

“We went to a village to teach students in a school. I felt that although those students lived in poor families and could only study half-day class, they cherished their learning opportunities very much. You could see their big differences from Hong Kong students, in terms of their learning attitudes and respect to their teachers. This made me reflect that I have wasted a lot of time through skipping classes or wondering in the campus when I have so good opportunity to go to study in university. This reflection changed my mind that I should try my best in my university study.”

Critical Thinking and Problem-Solving Skills

GUR subjects offered in different years all helped to promote the development of students' critical thinking. Based on students' narratives in different years, teachers in different GUR subjects such as Freshman Seminar did not merely teach subject knowledge but tried to inspire students' critical thinking consciously. For example, in an interview of the 2014-2015 academic year (i.e., students' third-year study), a student still clearly remembered how his first-year Freshman Seminar subject teacher inspired his critical thinking: "I still remembered that my teacher said 'the chair you are now sitting on is not just a chair.' He taught us in this approach in almost every class, to try to promote our thinking." Other subjects also promoted students' development of critical thinking. For example, the study of CAR subjects in different knowledge areas helped students to understand intellectual approaches of different disciplines. Students find that "Tomorrow's Leaders" subject not only covered sufficient theories but also allowed students to think critically. Besides, Service Learning subjects also helped students to develop critical and multi-perspective thinking. Some students shared that in planning and conducting a service project, they learned to consider one issue from different perspectives. For example, a student having joined a Service Learning subject on cultural conservation in an oversea district reflected:

"From the cultural aspect, our service project was only a cultural conservation project. However, it is also linked to the economic aspect since the local government had an urgent need to develop the local economy and too much emphasis on economic development might do harm to the local culture."

Besides, students' narratives indicating that some GUR subjects also promoted the development of students' problem-solving skills. Particularly, students' consistently agreed that the hands-on projects in Freshman Seminar subjects and service experiences in Service Learning subjects were conducive to their problem-solving skills. The common aspect of these subjects was that they provided complex real-problem contexts for students to solve problems effectively and innovatively, which is as one student said: "Service Learning subject helped me a lot. There were many unexpected situations that we need to modify our plan. This actually is problem-solving." In another case, another student also said:

"We finally went to Cambodia to develop a map for local people based on testing local soil and water. I think we practiced innovative problem-solving through this project. This is because that we needed to use some test instruments in doing the project, while we could not find these instruments in local place and also could not bring these instruments from our University to Cambodia. Under this circumstance we have to find some solutions to this problem, to think of some innovative ideas."

Other Aspects of Student Development

Besides the above developments, students' narratives in different years also revealed that the GUR program helped with development of mental and physical health, self-efficacy, and friendship and social network of different students. Some students consistently claimed that "Tomorrow's Leaders" helped to improve their mental health and self-efficacy. For example, one student shared that "my mental health has improved. Throughout 'Tomorrow's Leaders' subject, I realized actually we should hold positive attitudes towards everything and should

not be too negative.” “Tomorrow’s Leaders” subject also helped students to build their inner powers and increased their self-efficacy in general and in pursuing their academic study. For example, several students said that the subject taught them “how to cope with and bounce back to adversities” and how to “change” themselves for a better personal development, which made them “more positive to study their majors” because “I have realized that I should strive hard to study in the four years”. Furthermore, among all GUR subjects, with their general-education-based course nature, involved different students in the class and learning, which greatly increased students’ social interaction with peers from other departments and knowledge backgrounds. This helped many students to broaden their social networks and were perceived as useful for students’ future development. For example, one student said:

“My groupmates in ‘Tomorrow’s Leaders’ subject helped me a lot not just in this subject. For example, some male groupmates’ mathematics is very good. They helped me a lot on calculus. In turn, for some who take the CAR subjects that I have already studied in the last semester, I could give some advice to them.”

Application to Life and Helpful to Future Development

Across the four years, a number of students perceived that the knowledge, skills, or learning experiences they have gained from different GUR subjects could be applied in their daily life or could be helpful to their future development. For example, students perceived that their group work experiences in GUR subjects in early university years prepared for their group work in major studies in later university years. Also, students from non-business disciplines perceived that the business planning knowledge they learned in Freshman Seminar subjects were helpful to their future career development since their professions had interconnection with business fields. For example, one student from engineering discipline expressed that the business plan gave him “a good foundation” because “our engineering profession would have some relationships with business sectors, we can use this knowledge (business plan) if we would like to run business in engineering field in future.” Students also commonly perceived that the academic writing skills such as referencing skills learned from English language and communication subjects were very useful to their writing tasks in major subjects. Furthermore, there were students who benefited from “Tomorrow’s Leaders” subject, perceiving the subject helped their leadership in reality and self-reflection. In an interview, a student expressed that leadership knowledge was very important to him because he took several leadership roles in student societies and church work. He expected to learn leadership knowledge and skills from “Tomorrow’s Leaders” subject and then “Finally, it turned out that through the subject I really learned a lot, comprehend a lot, and reflected a lot. This facilitated my development.”

Students’ General Impressions of Their University Study

Students were also asked about their general impressions of their university study in interviews of longitudinal evaluation study. Overall speaking, students’ views were highly positive. The majority of the students perceived their university study as “fulfilling”, “enriching”, and “rewarding”. Some also used “busy but happy”, “changing”, “exploring”,

and “enjoying” to describe their four-year university life. Some students perceived that the four-year university study, with different subjects including GUR and major subjects, helped them to pursue their personal and professional goals. Many students commended that the University provided them many different learning opportunities such as service learning and oversea exchange and different activities to enrich their life and build their multiple abilities, which helped shape their future competitiveness in society. Some students also perceived that during their four-year university study, they had chances to meet and communicate with students from different backgrounds. Students’ positive views can be illustrated by the following Chinese narratives translated in English:

“I think the university is a place that helps you to realize or get close to your dreams. As I have said earlier, since I want to help people, I chose physiotherapy as my major. Then the service learning project in Cambodia made me realize more about the meaning of my Major. So the four-year university life made me closer to my dream and developed my different abilities such as communication, leadership and problem-solving. These were very useful to my future profession.”

“I feel hard but rewarding. This rewarding is not only on the grade but also on how to get along with people and dealing with things. These interpersonal experiences are so treasurable, which cannot be gained elsewhere. But the University provided these opportunities to us, for us to train ourselves. Therefore we could arm ourselves better to compete with others in future.”

“Very enriching! Almost in every year, I could be able to use the opportunities provided by the University to go to exchange in different places and to join different activities. I have been to Japan, Taiwan and Cambodia. Every time I could learn different things. This helped to prepare for our future career because we will not feel so challenging in doing different things in our workplace in future if we have already tried so many different things. So my four-year university life was very enriching and I have explored different things in this life.”

“Before enrolling in the University, I was not clear about my future goals. But after the four-year study, I find that I have not only got more understanding about my profession but also a clearer conception about my future directions. Also, I have learned and improved a lot in interpersonal skills in the University.”

“My university study was enjoyable and worthwhile. I was not just sitting in the classroom to read the textbooks every day. The GUR subjects, such as the Service Learning subject, provided me a lot of different experiences to apply our knowledge into helping the community. This made me feel that I have the ability to contribute to the society and to help people living in different conditions. I feel that my horizons have been broadened and my knowledge learned is applicable. These life experiences are so good and valuable to me.”

Challenges

Although students over the four academic years generally had positive views of the GUR and perceived the GUR program as effective in promoting students’ all-round development, they indicated challenges in studying GUR subjects. Three major challenges were noted by the students. First, although students perceived that many GUR subjects incorporated innovative and engaging pedagogy, they noted that there were still few courses adopting a big-class and mere-lecturing teaching method, which made their learning process boring and ineffective. For example, one student expressed in an interview “when I came in the class, the classroom was very dark and there were so many students there. Only one teacher stood far away speaking.” Another student also shared in another interview that “the content (of lectures of a CAR subjects) was very introductory. There was a far distance between the lecturer and us, and the lecturer was just speaking for himself, regardless of whether we listened to him or not.” Second, a number of students indicated that they could not register their interested CAR subjects because a large part of their timetables was occupied by their major subjects and most of their interested CAR subjects had timetable conflicts with their pre-assigned major subjects. Third, some students in their early university years showed an

unclear understanding and unfamiliarity with the course objectives and rationales of the GUR, which hindered their active participation and learning in these subjects. They expected to be given clearer information about the rationales and objectives of the GUR and its different subjects at the very start of their learning.

DISCUSSION

This study investigated students' perceptions of the General University Requirements (GUR) at The Hong Kong Polytechnic University (PolyU) and their developments under this new general education framework over the four academic years. This study was one component of a five-year longitudinal evaluation project to evaluate the effectiveness of the GUR at PolyU. Results showed that students improved in different aspects of developments under the GUR and held positive views of different aspects of GUR program. These results were consistent with the other quantitative and qualitative findings gained from other evaluation components of the project [18-24], which suggests a general effectiveness of the GUR in promoting students' holistic development and the development in the five desired graduate attributes of PolyU.

The findings of the present study have broad implications to the general education implementation and effectiveness in different higher education institutions. Particularly, broad literature on general education suggests that although general education was perceived as important by many educators, scholars, philosophers, and university administrators for centuries for developing all-round persons and broad-based professionals for a changing society, its implementation in higher education encounters increasing challenges in an age marked by over-proliferation and over-division of knowledge, science and university disciplines [25-27]. Against this, the reform and implementation of the GUR at PolyU provided experiences and references for other higher education institutions about implementation of general education in undergraduate education.

Several important observations can be gained from the findings of the present study. Firstly, results of the present study indicated that the GUR at PolyU incorporated large amount of elements of innovative and engaging teaching, and interactive and experiential learning. These new course modes and pedagogies were shown as the key determinants to students' engaged learning in the GUR and their development of important competencies through GUR subjects. Instead, the fewer courses adopting mere-lecture teaching method were criticized by students as less engaging and less effective in GUR. This observation is consistent with the general literature, which suggested that some engaging pedagogy or high impact practices in general education or liberal arts education such as service learning, capstone courses, first-year seminar, and collaborative learning and others had highly positive impacts on students' learning and development of desired learning outcomes [28-30]. In conjunction with the existing literature, the present study further supports the idea that the teaching and learning modes rather than the knowledge were key factor to successful general education program. Thus, university administrators and curricular reformers should focus more on how to develop innovative and engaging teaching and learning modes than on debating what and how many knowledge should be included in a general education program

[31, 32]. The recent reform trends on general education in different higher education institutions have further strengthened this argument [33-35].

Secondly, the present study indicated that students' clear knowledge about the objectives of the GUR and the subject registration mechanisms were also important factors impacting their learning motivations and effects in the general education. Students' unclear knowledge about the course rationale would hinder their active participation in learning. University administrators and general education subject teachers should pay more attention to how to clearly deliver the messages of their course objectives to their students before their learning. Students' failing to register their interested subjects would also greatly diminish their learning motivation and interests. However, there was not much literature concerning how to design selection mechanisms of elective subjects in general education to maximize students' course selection effects. More research is needed in this area for promoting a better functioning of different general education programs.

Thirdly, students' overall experiences about their four-year university education were very positive. One major contribution to this was the multiple learning experiences provided by the GUR program, such as the overseas service learning experiences. This was also in line with some literature suggesting that although students perceived their specialized studies highly, they valued a good and valuable general education as well and expected university provide broader and diversified learning experiences [36-38]. In conjunction with these existing findings, the findings of this study not only help to support the success of the GUR at PolyU, but also further indicate the importance and value of general education in modern universities.

Although the current study is pioneer in nature, limitations of the present study should be noted. Although the four-year longitudinal case study gained rich results about how students develop and perceive the GUR during their four-year university study, its data were subjective and still need to be combined with results from objective outcome evaluation such as objective survey and competency tests to determine the effectiveness of the GUR. Also, the present study only followed the first cohort of students enrolled in PolyU new curriculum, the views of students enrolled in later academic years should also be investigated. Despite the limitations, the present study explored students' development under the general education program in a longitudinal case study approach, which was pioneering in its methodology in field of evaluating effectiveness of general education.

ACKNOWLEDGMENTS

ABSTRACT

The General University Requirements (GUR) at The Hong Kong Polytechnic University (PolyU) is an integral part of the new 4-year undergraduate curriculum which attempts to promote holistic student development. To evaluate the effectiveness of the GUR, a study adopting a static group comparison design was adopted, with a sample of Year 3 PolyU students studied in the 4-year undergraduate degree program (N = 566) compared with a control Year 3 sample recruited from a comparable university in Hong Kong (N = 285). The students in both samples responded to measures on empathy, positive youth development, and engagement in university study. Results showed that although both groups basically did not differ in the major background demographic variables, PolyU students performed better than did the students of the control group on measures of holistic development. Bearing in mind the intrinsic problems of the static comparison group design, the present findings provide support for the effectiveness of the GUR at PolyU.

INTRODUCTION

Nowadays, the society has strong expectation for the higher education sector to nurture students the ability of solving real-world issues and meeting the needs in our community through instruction, research, or community partnership [1]. With the changing economic structure from manufacturing economies to knowledge-based economies, university graduates are expected not to just have narrow professional knowledge, but also general education, creativity, and problem-solving skills. In fact, many employers would regard soft skills (such as emotional management and cooperation) as more important than professional skills in university graduates. As argued by Baker, university education should be “much more than a production line for work-ready graduates” [2]. Similar view was held by Lewis who proposed that the core business of undergraduate training is to “... help them [students] grow up, to learn who they are, to search for a larger purpose for their lives, and to leave college as better human beings” [3].

How can we nurture university students in terms of general education and soft skills? In the North American university systems, it is commonly achieved through general education programs where students are exposed to knowledge of different disciplines, including humanities and social sciences. It is assumed through such “general exposure,” students can develop a broader and more flexible mind-set. Typically, general education may include language enhancement subjects, freshman seminars, and subjects in different disciplines such as human development, social development, globalization, history and philosophies, and science and technology. For some universities, they may have other requirements such as service learning, leadership programs and healthy lifestyle programs. As commented by the Task Force on Higher Education and Society [4], general education is “an excellent form of preparation for the flexible, knowledge-based careers that increasingly dominate the upper tiers of the modern labor force. With knowledge growing at unprecedented rates, higher education systems must equip students with the ability to manage and assimilate greatly expanded quantities of information.”

With specific reference to Hong Kong, the structure of the undergraduate university education has been changed from a 3-year to 4-year one since 2012-13 academic year. Before July 1, 1997, as Hong Kong was a British Colony, its education system was modelled after the British model, with five years of secondary school education, two years of matriculation education, and three years of university education. As there were many criticisms against the old education system modelled after the British system and propositions for aligning the system with the higher education system in China and North American, the old British system was changed in 2006 with three years of junior secondary school education, three years of senior secondary school education, and four years of university education. For the four year undergraduate university education, it began in 2012-13 academic year.

This education reform is regarded as “an important watershed for Hong Kong education as well as a unique opportunity for universities to move from a specialized focus to a more holistic student-oriented approach to undergraduate education” [5]. As advocated by the University Grants Committee (UGC), “having an additional undergraduate year will enable students to have more time and space to build a broader knowledge base and a more solid foundation for whole-person development. This will be conducive to the nurturing of capable talents to underpin the development of a knowledge-based economy as well as to meet the

rapid-changing needs of the society” [6]. According to UGC, “the rationale of the new curriculum is to provide students with greater flexibility, more broad-based and student-centered learning experience. Institutions have put in extraordinary efforts to ensure that the four-year undergraduate programme, which comprise the core, major and elective courses with an emphasis on general education and exposure to both academic and non-academic skills and knowledge, will be coherent, and the additional year is not simply an add-on to the current three-year undergraduate programme.” [7]

To achieve the above expectations, The Hong Kong Polytechnic University has formulated a General University Requirements (GUR) initiative which formed an integral part of the new 4-year undergraduate curriculum commencing from 2012-13 academic year. In the new 4-year curriculum, GUR study of the students includes Freshman Seminar (3 credits), Language and Communication Requirements (9 credits), Cluster Area Requirements (12 credits), Leadership and Intrapersonal Development (3 credits), Service Learning (3 credits), and Healthy Lifestyle (0 credit). By doing this, PolyU graduates are expected to not only attain professional competence in their areas of professional training, but also develop core competence of employability and civility to be responsible and contributing members of our society. The University has refined the general student learning outcomes and arrived at six major desired attributes for graduates. In addition to professional competence, five other attributes are highlighted including critical thinking, effective communication, problem-solving, lifelong learning, and ethical leadership. It is expected that the GUR can contribute to the development of these five qualities in the students.

Although the design of the GUR is conceptually elegant and noble, there is a need to understand whether and how the GUR works well. To investigate the changes in the undergraduate students with respect to the above desired attributes under the 4-year undergraduate curriculum, the University awarded a Teaching Development Grant to a Research Team of colleagues to review and evaluate the GUR study in 2012-13 academic year, with the first author as the principal investigator and the second author as the co-principal investigator. The research adopts a five-year longitudinal mixed-method design. Quantitative methods included online surveys addressing student-level developmental indicators (objective outcome evaluation), students’ feedback questionnaires on GUR subjects (subjective outcome evaluation), and the Collegiate Learning Assessment (CLA+) (objective outcome evaluation). Qualitative methods included document analysis and focus group interviews with different stakeholders (review of the offering and implementation of the GUR and qualitative evaluation).

Is the GUR effective in promoting the holistic development of the students? To date, some evaluation findings showed that students had positive evaluation of the GUR components and its perceived benefits. Shek, Yu, Wu and Ng [8] examined the implementation and impact of GUR components. Evaluation based on different approaches revealed that students had favorable evaluation of the subjects, teachers and benefits of the GUR. Besides, students generally held the view that GUR subjects could promote the problem-solving, critical thinking, effective communication, ethical leadership and lifelong learning attributes in students (i.e., desired PolyU graduate attributes). Shek, Yu and Ngai [9] examined students’ feedback using the Student Feedback Questionnaires. The subjective outcome evaluation findings generally showed that the students had positive views of the GUR subjects, teachers and the benefits. Furthermore, Shek, Yu, Wu and Chai [10] conducted focus group interviews to collect views of 62 students on GUR subjects. It was found that the

GUR (subjects, teachers and benefits) component of the 4-year curriculum was well-received by the students. The students also appreciated the interactive teaching and learning methods used in GUR subjects.

Obviously, although the existing evaluation findings are positive, they are based primarily on subjective outcome evaluation and qualitative evaluation. Hence, it would be desirable to look at the effectiveness using objective outcome evaluation data. As such, a study based on a static group comparison design was carried out. A static group comparison design is a pre-experimental design which is commonly used in social sciences research. In this design, there is a treatment group as well as a control group without baseline assessment. The differences between the two groups are then compared at some subsequent time. There are several advantages of this design. First, it can be used in a convenient manner in many contexts where data on a large number of variables and subjects are collected. Second, in contrast to classical experimental designs, the related procedures in the static group comparison design are simple. For a treatment group, what is needed is a control group possibly through matching the background socio-demographic attributes. Third, in cases where randomization is not possible, static group comparison can help to generate hypotheses and serve a good purpose as an exploratory research.

On the other hand, there are several disadvantages of a static group comparison design. First, as it is a cross-sectional study, it does not permit the researchers to look at changes across time. Second, as there is no real “control” of the experimental condition, it is not possible to establish the cause-effect relationship. Third, there are rival explanations for the differences between the experimental group and control group. For example, it can be argued that the differences between the two groups are due to differences in socio-demographic factors. Although such differences in confounding can be dealt with through statistical analyses, there are always the logical possibility that the two groups are different in terms of other factors not included in the study [11].

Researchers in many fields have used the static group comparison design for program evaluation. Odundo, Anjuri and Odhiambo [12] used a static group comparison design to examine the influence of peer education on behavior change in secondary education and HIV/AIDs. The basic research design was to compare those who joined peer education club and those who did not in terms of their sexual behavior and HIV testing. While acknowledging the limitations of the study design such as confounding factors, the authors concluded that the intervention promoted abstinence in sex, faithfulness to a partner, use of condom and testing for HIV. Another example is from the work of Moodley, Kritzinger, and Vinck [13] who investigated the effect of play-based versus formal instruction on English language proficiency using a static two-group comparison design. The researchers showed that the formal approach had better effect than the play-based approach on the English test scores.

In this study, the impact of GUR on student development was examined via a two-group static group comparison method. For the “treatment” group, Year 3 students studying in the 4-year undergraduate degree program were recruited. For the “control” group, Year 3 students studying in a 4-year undergraduate degree program in a comparable university in Hong Kong were invited to participate in the study.

OUR STUDY

The participants of the “treatment” group (i.e., PolyU group) were Year 3 students under the 4-year curriculum who had participated in a longitudinal evaluative project on GUR at PolyU. Based on stratified random sampling method, 643 students were initially selected from eight faculties and schools at PolyU in 2012-13 in terms of the faculty-based proportions of First Year First Degree (FYFD) intake in that year. These students were invited for the third time to respond to the GUR online survey in November of 2014. A total of 566 students (response rate = 88.02%) completed the survey via the electronic system.

Table 1. Comparison of background variables between PolyU and ControlU participants

		PolyU	ControlU	Comparison	Effect size
Gender ^a	Male	235(41.5%)	106(37.2%)	$\chi^2 = 1.67$, $df = 2$, $p = .43$	-
	Female	327(57.8%)	176(61.8%)		
	Not indicated	4(0.7%)	3(1.0%)		
Parental marital status ^a	Divorced	53(9.4%)	20(7.0%)	$\chi^2 = 4.07$, $df = 4$, $p = .40$	-
	Separated	8(1.4%)	5(1.8%)		
	Married (First marriage)	473(83.6%)	238(83.5%)		
	Married (second marriage)	12(2.1%)	5(1.8%)		
	Others	20(3.5%)	17(6.0%)		
Family economic status ^a	CSSA recipient	45(8.0%)	19(6.7%)	$\chi^2 = 0.48$, $df = 2$, $p = .79$	-
	Non-CSSA recipient	492(86.9%)	252(88.4%)		
	Not indicated	29(5.1%)	14(4.9%)		
Academic Field ^a	Business	136(24.0%)	75(26.3%)	$\chi^2 = 6.88$, $df = 3$, $p = .08$	-
	Art & Social Science	155(27.4%)	55(19.3%)		
	Science & Engineering	258(45.6%)	147(51.6%)		
	Design & Media	17(3.0%)	8(2.8%)		
Perceived family life satisfaction ^b		3.77(0.88)	3.80(0.83)	$t = -.42$, $df = 849$, $p = .68$	-
HKDSEE results ^b		Omnibus Multivariate Test: $F(4, 699) = 10.12$, Wilk's Lambda = 0.97, $p < .01$			
	Chinese	4.23(0.93)	3.98(0.80)	$F = 11.93$, $df = 1, 702$, $p = .01$	$\eta^2 = .02$
	English	4.01(0.83)	4.10(0.73)	$F = 1.76$, $df = 1, 702$, $p = .19$	-
	Mathematics	4.46(0.90)	4.13(0.69)	$F = 23.01$, $df = 1, 702$, $p < .01$	$\eta^2 = .03$
	Liberal Studies	4.17(0.81)	4.15(0.86)	$F = 0.06$, $df = 1, 702$, $p = .81$	-
Age ^b		20.12(0.57)	20.28(0.90)	$t = -3.10$, $df = 848$, $p < .01$	Cohen's $d = 0.21$

Note:

^aCategorical variables: values outside parenthesis were numbers of participants and values in parenthesis were the related within-group percentages.

^bContinuous variables: values outside parenthesis were means and values in parenthesis were standard deviations.

CSSA denotes CSSA denotes Comprehensive Social Security Assistance Scheme.

For the participants of the “control” group, quota sampling was adopted to select students of the same cohort from a comparable university in Hong Kong, based on the proportion of students from each faculty/school. Considering the difference in the institutional structure of the two universities, the eight faculties of PolyU were re-grouped into four academic fields for better alignment, namely Business, Arts and Social Science, Science and Engineering, Design and Media. In total, 290 Year 3 students under the 4-year curriculum in the comparable university (named as “ControlU” in this paper) were selected and invited to complete the GUR online survey at the same time period. Two hundred and eighty five participants completed the questionnaire on time (response rate = 98.28%).

Basic demographic information for the experimental group (N = 566) and the control group (N = 285) is shown in Table 1. In total, 341 participants were male and 503 participants were female. The majority of the respondents were 20 years old (N = 626; 74%), living with parents of first marriage (N = 461; 85%), and from a family with an average income (N = 711; 84%). Statistical analyses were conducted to compare the background variables between the two groups and the results generally showed that the two groups were generally equivalent, except their scores on the university entrance examination and age (see Table 1).

Written consent was obtained from the students before they responded to the questionnaire. Participating students were administered the GUR online survey through the MySurvey@PolyU electronic survey system in November of 2014. Students could choose to complete the survey at home or in a preserved computer room at PolyU. Research purposes and detailed instructions about how to complete the questionnaire were explained to students by several rounds of email and further announced on the survey webpage. It took around 40 minutes to complete the whole questionnaire. Respondents’ electronic answers were directly downloaded as a SPSS file for statistical analysis.

The questionnaire included several validated scales and a few items on participants’ demographic information. The present study would focus on three major scales including the Chinese Interpersonal Reactivity Index (C-IRI), Chinese Positive Youth Development Scale (CPYDS), and National Survey of Student Engagement (NSSE). The three scales and their subscales measure students’ developmental outcomes in relation to five desired university graduate attributes (i.e., problem-solving, critical thinking, lifelong learning, ethical leadership, and effective communication). The alignment between the three scales and the attributes was shown in Table 2.

- *Chinese Interpersonal Reactivity Index (C-IRI)*: It is a self-reported questionnaire designed to assess different components of empathy in Chinese population validated by Siu and Shek [14] based on Davis’s [15] work. The C-IRI comprises 22 items which further constitute three subscales: Empathy (11 items), Fantasy (4 items), and Personal Distress (7 items). Using a four-point Likert scale, scores for each domain are expressed in terms of average domain items scores. High C-IRI score represents for high level of empathy which is an essential quality of ethical leadership and effective communication. In the present study, the three composite scores of C-IRI were calculated and compared between the two groups. Cronbach’s alpha coefficients for the C-IRI on the experimental group and control group were 0.80 and 0.82, respectively.
- *Chinese Positive Youth Developmental Scale (CPYDS)*: It was developed by Shek, Siu, and Lee [16] to measure positive characteristics and developmental assets in

Chinese adolescents. In the present study, a selection of 14 major subscales from the CPYDS were adopted to measure participants' development, including Problem-solving (3 items), Resilience (3 items), Social Competence (3 items), Emotional Competence (3 items), Cognitive Competence (4 items), Behavioral Competence (2 items), Moral Competence (3 items), Self Determination (2 items), Life-Long Learning (2 items), Self-Efficacy (2 items), Ethical Leadership (15 items), Critical Thinking (3 items), Self-Leadership (5 items) and Life-Satisfaction (5 items). Items of Self-Leadership subscale were rated on a five-point Likert scale while all other items were rated on a six-point Likert scale. Subscale scores were expressed in terms of average domain items scores. Higher scores mean higher level of positive youth development. The 14 subscale scores (composite scores) of CPYDS were computed and compared across the two groups in the present study. Cronbach's alpha coefficients of the CPYDS for the experimental group and control group were 0.95 and 0.96, respectively.

- *National Survey of Student Engagement (NSSE)*: Students' engagement in learning and other university experience was assessed with a locally adapted version of the National Survey of Student Engagement (NSSE) [17]. The NSSE has been administered and validated in both the United States [18] and mainland China [19, 20] with good psychometric properties. The NSSE evaluates students' university experiences in terms of 11 major indexes: Collaborative Learning (4 items), Reflective and Integrative Learning (7 items), Student-Faculty Interactions (4 items), Higher-Order Learning (4 items), Effective Teaching Practices (5 items), Quantitative Reasoning (3 items), Discussions with Diverse Others (4 items), Learning Strategies (3 items), High-Impact Practices (6 items), Quality of Interactions (5 items), and Supportive Environment (8 items). Responses on the adapted NSSE were measured based on a four-point Likert scale except items of Quality of Interactions (7-point Likert scale). Composite scores for each NSSE domain were expressed in terms of average index items scores. The present study compared the 11 composite scores across the two groups. Cronbach's alpha coefficients of the adapted NSSE for the experimental group and control group were 0.86 and 0.91, respectively.

Table 2. Relationships between instruments and desired university graduate attributes

Desired Attributes	Instruments		
	C-IRI	CPYDS	NSSE
Problem-solving		√	
Critical thinking		√	
Life-long learning		√	√
Ethical leadership	√	√	
Effective communication	√	√	√

Note:

C-IRI = Chinese Interpersonal Reactivity Index;

CPYDS = Chinese Positive Youth Development Scale;

NSSE = National Survey of Student Engagement.

FINDINGS

Background variables of the two groups were first compared before the comparison on key developmental indicators was made. For categorical variables including gender, family economic status, and parental marital status, a series of chi-square tests were conducted. For continuous variables including age and perceived family life satisfaction, t-tests were performed to examine the group differences. In addition, to examine whether the two groups were differ in their academic performance when they first entered into University, grades in four major areas in HKDSEE (the Hong Kong Diploma of Secondary Education Examination) were compared by employing MANOVA.

As shown in Table 1, the results showed that there were no significant group differences in participants' gender ratio ($\chi^2 = 1.67$, $p = .43$), parental marital status ($\chi^2 = 4.07$, $p = .40$), family economic status ($\chi^2 = 0.48$, $p = .79$), and perceived family life satisfaction ($t = -.42$, $p = .68$). In other words, for these demographic variables, the two groups of students can be regarded as equivalent.

As for the university entry grade, PolyU students scored higher than ControlU students in Chinese and Mathematics, and no significant differences were identified in English and Liberal studies. Partial eta squares were further calculated for the two variables with significant differences and the results (see Table 1) suggested small effect sizes based on the criterion given by Miles and Shevlin [21]. This indicates that participants from the two universities had similar level of academic performance when they first entered into University. The only significant difference in demographic variables between PolyU and ControlU participants was found in students' age ($t = -3.10$, $p < .01$, Cohen's $d = 0.21$). PolyU students (mean age = 20.12, standard deviation = 0.57) were slightly younger than students of ControlU (mean age = 20.28, standard deviation = 0.90). According to the rule of thumb proposed by Cohen [22], the effect size could be regarded as small. Given that all participants were sampled from the same cohort/grade, and that the minor difference in age is unlikely to influence students' development in their University study, age would not be controlled in the following analyses.

Group Comparison in Developmental Indicators

To compare the development of students from the two universities in different areas, a series of t-tests were conducted on participants' scores of the three scales and their subscales. Table 3 presented the means and standard deviations of participants' scores for PolyU group and ControlU group as well as the statistical results of t-tests. As can be seen in the table, the two-tailed tests showed that nine variables displayed significant group differences including Cognitive-Behavior Competence, $t(566) = 2.44$, $p < .05$, Problem-solving, $t(566) = 2.10$, $p < .05$, Emotional Competence, $t(566) = 2.94$, $p < .05$, Cognitive Competence, $t(566) = 2.44$, $p < .05$, Behavioral Competence, $t(566) = 2.04$, $p < .05$, Moral Competence, $t(566) = 2.07$, $p < .05$, Life Satisfaction, $t(566) = 2.58$, $p < .05$, Learning Strategies, $t(566) = 2.99$, $p < .05$, and Quality of Interactions, $t(566) = 3.02$, $p < .05$. PolyU students performed better than ControlU students in all the nine indicators.

Supportive Environment	566	2.52	0.57	285	2.47	0.55	1.21	849.00	.23

Note: * means $p \leq .05$ (two-tailed); ^ameans $p \leq .05$ (one-tailed); ns means non-significant.

Total CPYDS Score = Total score of the Chinese Positive Youth Development Scale; Cognitive-Behavioral Competence = the composite score of a second-order factor based on subscales of Cognitive Competence, Behavioral Competence, and Self-Determination.

By adopting a one-tailed test of significance, it was further found that PolyU participants also scored higher than ControlU students on Self Determination, $t(566) = 1.77$, $p = .08$; while ControlU participants scored higher than PolyU participants on Student-Faculty Interactions, $t(566) = -1.67$, $p < .05$, and High-Impact Practices, $t(566) = -1.91$, $p < .05$. These findings suggest that PolyU participants showed higher levels of cognitive-behavioral competence, emotional competence, moral competence, problem-solving ability, life satisfaction, and self-determination than did their ControlU peers. In terms of university engagement, PolyU students also reported more positive interpersonal relations in university environment and

more effective learning strategies than did ControlU students. Meanwhile, PolyU students rated their degree of interaction with faculty members and participation in practices designated as having higher impact on their development slightly lower than ControlU students. These findings overall suggest a better developmental outcome in PolyU participants as compared to ControlU students in the same cohort after two-year University study.

DISCUSSION

The primary objective of this study was to examine the effectiveness of the 4-year undergraduate curriculum implemented at PolyU by comparing the Year 3 PolyU students and Year 3 students of a comparable university in Hong Kong. Several strengths of this study are noted. First, this is the first known scientific study examining the effectiveness of the general education component of the 4-year undergraduate program using objective outcome evaluation. Second, a static group comparison design was used to compare the Year 3 PolyU students and a control group. Third, validated measures of empathy, positive youth development and university engagement were employed. Finally, the findings give support to the original hypotheses.

Consistent with the general hypothesis, the present findings show that students in the treatment group performed better than did students in the control group. Generally speaking, PolyU students did better than the control group students on several indicators on positive youth development and student engagement. These findings are consistent with the other evaluation findings based on student feedback questionnaires and qualitative evaluation strategies that GUR was able to promote the holistic development of university students. In particular, psychosocial competence in PolyU students was higher than that of the control group students. As soft skills are of paramount importance in knowledge-based economies, the finding that PolyU students had higher cognitive, emotional, behavioral and moral competence is encouraging. Besides, the higher level of life satisfaction in PolyU students is a sign suggesting that quality of life in PolyU students was relatively favorable.

While the findings are positive and they give support to the original hypotheses, several limitations of the study should be realized. First, the study can only give some clues to the cross-sectional differences between the two groups. As such, longitudinal data reflecting changes in the students should be collected in future. Second, as the sample in the control group was recruited through quota sampling, the generalizability of the findings may be questionable. Third, as the two groups slightly differed in age and university entrance examination results, further matching work could be carried out to ensure that the two samples are equivalent. Of course, by doing this, the tradeoff is reduction in the sample size. Besides, as the control group students were relatively older than the treatment group students, their differences in terms of maturation is not a viable explanation. In short, despite the intrinsic problems of a static group comparison design, the present study provides some support to the claim that the GUR component at The Hong Kong Polytechnic University is beneficial to the holistic development of the students studying in the new 4-year undergraduate program.

ACKNOWLEDGMENTS

The preparation for this paper and the GUR evaluation study are financially supported by the Teaching Development Grant of The Hong Kong Polytechnic University. The authorship is carried equally by the first author and second author. This chapter is based on a paper to be published in the *International Journal of Adolescent Medicine and Health*.

ABSTRACT

The undergraduate curriculum structure in Hong Kong was changed from three years to four years starting from 2012-13 school year, with the extra year of study primarily devoted to general education study. At The Hong Kong Polytechnic University (PolyU), the General University Requirements (GUR) has been designed in response to this change. In this study, the question of whether the development of students in the 4-year program was better than that of the 3-year program was examined via a static group comparison design. The treatment group was third-year students of the 4-year undergraduate degree program (N = 566) whereas the control group was comprised of third-year students of the 3-year degree program (N = 290). Measures on empathy,

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

positive youth development, and student engagement were used as indicators of student holistic development. While the mean age of students in the 3-year program was higher than that of the 4-year program, students in the 4-year program performed better than did the students of the 3-year program on several indicators of desired graduate attributes. Bearing in mind the limitations of the static comparison group design, the present study provides support for the positive impact of GUR at PolyU on students of the 4-year undergraduate curriculum.

INTRODUCTION

There are different types of undergraduate degree programs in different parts of the world. In the British and Commonwealth systems, three-year undergraduate degree programs are common. For example, in the case of United Kingdom, secondary school students are required to study for five years before taking the General Certificate of Secondary Education (GCSE). After that, they need to take two years of advanced level education before entering university, which normally offers three-year undergraduate program. On the other hand, the undergraduate degree program in North America is typically under a four-year structure. The general framework is three years of junior secondary school education, three years of senior secondary school education, and four years of undergraduate degree education.

With particular reference to Hong Kong, the education system was modeled after the British model before the handover of Hong Kong back to China in 1997. Secondary school students took five years of secondary school education before taking the Hong Kong Certificate of Education Examination. After that, they were required to take two years of matriculation education before taking the Advanced Level Examination. For university education, it was a three-year program except for some professional programs such as medicine. Although the education system at the Colonial time was quite successful to nurture elites for Hong Kong, the system had been severely criticized, such as morbid emphasis on academic excellence and creation of excessively high examination stress for the students. Hence, there was a call for education reform in Hong Kong after its handover in 1997. Eventually, there was a change in the education system starting from 2006. In the new academic structure, there are three years of junior secondary school education, three years of senior secondary school education, and four years of university education. The 4-year undergraduate curriculum has been formally implemented since 2012-13 academic year. The background and rationales of the education reform and the 4-year undergraduate curriculum can be seen from the reports of the Education Commission (EC) and the University Grants Committee (UGC). Some of the relevant quotes can be seen below:

- “Internationally, the academic structure and length of study in higher education have been evolving continuously to cater for the needs for life-long learning in a knowledge-based society. The common trend is to broaden the scope of learning in the universities and to defer the process of specialization. ... For many years, teaching staff of the higher education sector have been calling for a change to the academic structure of university education in the hope that students will be allowed more room to build up a broader knowledge base. This is in line with the trend mentioned above. This does not mean that the EC would like to see all first-degree

programmes adopting the same duration. A 3-year senior secondary academic structure does not necessarily require first degree programmes to be 4 years. However, if the students can enter university one year earlier, the universities will have more room in providing higher education” [1].

- “Universities are recommended to review the functions, contents, focuses and modes of teaching of their first-degree programmes, so as to strike the right balance between the breadth and the depth of such programmes. This would, in addition to helping students master the necessary knowledge and skills for specific professions/disciplines, give them exposure to other learning areas and help them develop a sense of integrity, positive attitude, a broad vision and important generic skills” [1].
- “The UGC strongly believes that all students stand to benefit significantly from the move to six years of secondary schooling and a normative four-year undergraduate programme as it will provide a more balanced, all-round and fulfilling learning experience that suits their different needs, aptitudes, abilities and interests. Having an additional undergraduate year will enable students to have more time and space to build a broader knowledge base and a more solid foundation for whole-person development. This will be conducive to the nurturing of capable talents to underpin the development of a knowledge-based economy as well as to meet the rapid changing needs of the society” [2].
- “The rationale of the new curriculum is to provide students with greater flexibility, more broad-based and student-centered learning experience. Institutions have put in extraordinary efforts to ensure that the four-year undergraduate programme, which comprise the core, major and elective courses with an emphasis on general education and exposure to both academic and non-academic skills and knowledge, will be coherent, and the additional year is not simply an add-on to the current three-year undergraduate programme” [3].

For the extra year under the 4-year curriculum, it was argued in the education reform process that general education would be beneficial to the holistic development of the students. On top of the Government views reflected in the reports by the Education Commission and University Grants Committee, there are arguments advanced by academics which are reflected in the following quotes:

- “Higher education has two dimensions – breadth and depth. Institutions are expected to instill both a breadth and depth of knowledge to insure that students will function effectively in their adult roles. The general education component is the breadth dimension and is usually defined on an institutional-wide basis, involving study in the several subject areas cited above” [4].
- “It is beyond all reasonable doubt that the universities have their share of responsibility for the well-being of the community. It is exactly because they have to face this responsibility, and because they do not run away from it, that they have to insist on the importance of a more general education. Life is more than technology, economics and commerce; life is even more than mere survival, and to learn the art of living has to be part of the education offered by the university” [5].

- “Undergraduate students are typically exposed to a wide range of subjects in their early college years. This gives them some conception of the foundations and forms of knowledge available to them. Then we require them to choose an area of concentration, a major subject, believing that the organized pursuit of knowledge brings special benefits. This approach differs from that of the dilettante by positing intriguing relationships among the different parts of a particular form of human understanding and demonstrating confidence that pursuing these relationships with sustained persistence bears its own fruit” [6].
- “We believe that the aim of education is not to teach students a vocation, because the vocations of the present will become obsolescent in the future; nor will the aim of education be merely to acquire knowledge, a futile enterprise when our knowledge and our knowledge base double virtually every decade. We believe in an education that involves training out students to think for themselves, to use what we know of the past to prepare them for the future, and to develop those skills and habits of insight and of imagination to solve problems and to resolve questions which are scarcely imaginable today. And those best equipped for the future will be self-sufficient and self-motivated individuals who can construct new solutions to old problems. And this is particularly true in the ‘new economy’” [7].

As a university funded by the University Grants Committee, the undergraduate program at The Hong Kong Polytechnic University (PolyU) was changed in 2012-13 school year. With reference to the 120-credit minimum graduation requirement, 30 credits are devoted to General University Requirements (GUR) which includes Language and Communication Requirements (9 credits), Freshman Seminar (3 credits), Cluster Area Requirements (12 credits), Leadership and Intrapersonal Development (3 credits), Service Learning (3 credits), and Healthy Lifestyle (0 credit). It is expected that the General University Requirements can promote the holistic development of undergraduate students, including effective communication, innovative problem solving, critical thinking, ethical leadership, and lifelong learning.

To what extent the four-year program contributes to the developmental outcomes of PolyU students? As it is not possible to randomly assign students to the three-year and four-year programs in the Hong Kong context, we might rely on pre-experimental designs. One possible design is to use a static group comparison design to compare students in the 3-year program with students in the 4-year undergraduate program. In this study, differences between students in the 3-year and 4-year programs at PolyU were investigated using a two-group static group comparison design. While the subjects in the “experimental” group were third-year students studying in the 4-year undergraduate degree program, subjects in the “control” group were consisted of third-year students (i.e., graduating students) studying in the 3-year undergraduate degree program at PolyU.

OUR STUDY

The current study adopted a static group comparison design. Participants included 566 third-year PolyU undergraduate students enrolling in the 4-year degree program

(experimental group) and 290 third-year students under the 3-year degree program at the same university (control group). The experimental group participants came from the 643 participants who were originally selected to participate in a five-year longitudinal evaluation research on the GUR from eight faculties/schools of PolyU in the 2012-13 academic year based on stratified random sampling. In the 2014-15 academic year, all 643 participants were invited to respond to the online survey for the third time. A total of 566 students (response rate = 88.02%) finally completed the survey. The control group participants were selected from third-year undergraduate students studying 3-year degree program in the 2014-15 academic year using quota sampling based on the basic characteristics (faculty and gender) of the experimental group participants. Out of 300 students being selected, 290 control group participants completed the online survey (response rate = 96.67%).

The demographic information of the participants is reported in Table 1. For the whole sample, there were 349 male students and 501 female students. The mean age of the participants was 21 years (age = 20.74 ± 1.16). The majority of them came from Non-CSSA recipient families ($N = 753$; 88.0%), and lived with parents in their first marriage ($N = 702$; 82.0%).

Written consent was obtained from the students before they responded to the questionnaire. Participants were administered the GUR online survey through the MySurvey@PolyU electronic survey system in November of 2014. Students could choose to complete the survey at home or in a preserved computer room at PolyU. Detailed explanations on the study and the rights of the participants (including withdrawal at any time they wished) were explained to students in the invitation e-mails and the survey webpage. Generally speaking, the participants took around 40 minutes to complete the questionnaire.

The students responded to different measures on the Internet. In the e-questionnaire, measures of empathy, positive youth development, student engagement, and socio-demographic characteristics were used. The scales adopted in this study included:

- *Chinese Interpersonal Reactivity Index (C-IRI)*: Based on the work of Davis [8], Siu and Shek [9] developed the Chinese version of the Interpersonal Reactivity Index. There are 22 items in C-IRI, including 11 items on empathy, 4 items on fantasy, and 7 items on personal distress, which are all rated on a four-point Likert scale. A higher C-IRI score represents a higher level of empathy. Reliability analyses showed that the total scale was reliable for both the experimental group and the control group ($\alpha = .80$ and $.82$, respectively).
- *Positive Youth Development Attributes*: To assess positive youth development in Chinese adolescents, Shek, Siu, and Lee [10] designed the Chinese Positive Youth Development Scale (CPYDS). Some of the subscales and items were included in this study. Besides, items assessing the desired graduate attributes were also included. The final scale included 3 items on problem solving, 3 items on resilience, 3 items on social competence, 3 items on emotional competence, 4 items on cognitive competence, 2 items on behavioral competence, 3 items on moral competence, 2 items on self-determination, 2 items on life-long learning, 2 items on self-efficacy, 15 items on ethical leadership, 3 items on critical thinking, 5 items on self-leadership, and 5 items on life satisfaction. The items were averaged to form subscale and total scale scores, with higher scores indicating higher level of positive youth development. Two composite scores of the CPYDS were also calculated and

compared, including the scale score of the CPYDS and the score of a second-order factor, cognitive-behavioral competence. Cronbach's alpha coefficients of the CPYDS were .95 and .96 for experimental group and control group, respectively, suggesting good internal consistency of the scale.

- *National Survey of Student Engagement (NSSE)*: The Chinese version of the National Survey of Student Engagement [11] was used to assess student engagement and learning in university education. Research findings showed good psychometric properties of NSSE in the United States [11] and China mainland [12, 13]. There are 11 major domains in NSSE, including Collaborative Learning (4 items), Reflective and Integrative Learning (7 items), Student-Faculty Interaction (4 items), Higher-Order Learning (4 items), Effective Teaching Practices (5 items), Quantitative Reasoning (3 items), Discussions with Diverse Others (4 items), Learning Strategies (3 items), High-Impact Practices (6 items), Quality of Interactions (5 items), and Supportive Environment (8 items). Results showed that the instrument in these two groups was internal consistent (alpha = .86 and .91 for experimental group and control group, respectively).

FINDINGS

The experimental group and control group were first compared on their demographic characteristics. Chi-square tests were carried out to examine group differences on gender ratio, family economic status, parental marital status, and faculty-based student proportion (see Table 1). Findings revealed that the two groups did not differ significantly in gender ratio ($\chi^2 = 0.39$, $p = .82$), family economic status ($\chi^2 = 0.11$, $p = .74$), parental marital status ($\chi^2 = 2.75$, $p = .10$), and the proportions of students from different faculties ($\chi^2 = 0.81$, $p = 1.00$).

Independent-samples t-tests were also performed to compare the two groups on age and perceived family life satisfaction (see Table 1). Results showed that the two groups did not differ significantly on their perceived family life satisfaction ($t = 0.29$, $p = .77$), while differed significantly on age, $t = -26.54$, $p < 0.01$, Cohen's $d = -2.09$. Control group participants (age = 21.94 ± 1.09) were older than the experimental group participants (age = 20.12 ± 0.57), which was expected. These results generally indicated that the experimental group sample and the control group sample were similar in their background characteristics.

Group Differences on Developmental Indicators

Independent-samples t-tests were carried out to compare the differences between the experimental group and control group on scores of the three scales and their subscales (see Table 2). Findings revealed that compared with the control group, participants in the experimental group scored significantly higher on two variables of the C-IRI including Empathy ($t = 2.84$, $p < .05$) and Fantasy ($t = 3.03$, $p < .05$), and eight variables of the measures of positive youth development, including Resilience ($t = 2.30$, $p < .05$), Emotional

Table 1. Comparison of background variables between PolyU third-year participants under 4-year and 3-year programs

		Total	PolyU 4YD	PolyU 3YD	Comparison	Effect size
Gender ^d	Male	349(40.8%)	235(41.5%)	114(39.3%)	$\chi^2 = 0.39$, $df = 2$, $p = .82$	-

	Age ^b	20.74(1.16)	20.12(0.57)	21.94(1.09)	$t = -26.54$, $df = 368.57$, $p < .01$	Cohen's $d = -2.09$

Note: PolyU 4YD = PolyU third-year participants under the 4-year program; PolyU 3YD = PolyU Year3 participants under the 3-year program.

^a Categorical variables: values outside parenthesis were numbers of participants and values in parenthesis were the related within-group percentages.

^b Continuous variables: values outside parenthesis were means and values in parenthesis were standard deviations.

^c Intact family = parents are married in their first marriage; Non-Intact family = parents are divorced/ separated/ married in their second marriage/ others.

^d Comparison was made on the ratio of CSSA recipient to Non-CSSA recipient between the two groups.

CSSA denotes Comprehensive Social Security Assistance Scheme.

FAST = Faculty of Applied Science & Textiles, FB = Faculty of Business, FCE = Faculty of Construction & Environment, FENG = Faculty of Engineering, FH = Faculty of Humanities,

FHSS = Faculty of Health & Social Sciences, SD = School of Design, SHTM = School of Hotel & Tourism Management.

Competence ($t = 4.11, p < .05$), Cognitive Competence ($t = 2.15, p < .05$), Behavioral Competence ($t = 2.28, p < .05$), Self Determination ($t = 2.04, p < .05$), Critical Thinking ($t = 1.63, p < .05$, one-tailed), Ethical Leadership ($t = 2.26, p < .05$), and Life Satisfaction ($t = 2.41, p < .05$). Besides, the experimental group performed better than the control group on seven variables of the NSSE including Collaborative Learning ($t = 2.15, p < .05$), Higher-Order Learning ($t = 1.99, p < .05$), Effective Teaching Practices ($t = 2.47, p < .05$), Learning Strategies ($t = 4.54, p < .05$), and Supportive Environment ($t = 2.14, p < .05$), Reflective and Integrative Learning ($t = 1.87, p < .05$, one-tailed), and Discussions with Diverse Others ($t = 1.77, p < .05$, one-tailed). Moreover, two composite scores of CPYDS, the CPYDS total score and Cognitive-Behavioral Competence score also showed that the experimental group performed better than the control group. However, control group had higher scores on High-Impact Practices ($t = -1.90, p < .05$, one-tailed) than the experimental group.

Note: PolyU 4YD = PolyU third-year participants under the 4-year program; PolyU 3YD = PolyU third-year participants under the 3-year program.

*means that $p \leq .05$ (two-tailed); ^a means that $p \leq .05$ (one-tailed); Total CPYDS Score = Total score of the Chinese Positive Youth Development Scale; Cognitive-Behavioral Competence = the composite score of a second-order factor based on subscales of Cognitive Competence, Behavioral Competence, and Self-Determination.

DISCUSSION

This study was conducted to investigate the impact of the 4-year undergraduate curriculum on PolyU students by comparing the developmental outcomes in third-year students in the 4-year program and third-year students in the 3-year program. Several unique features are intrinsic to this study. First, this is the first known scientific study which compared the 4-year degree program and 3-year degree program in the context of education reform in Hong Kong. Second, the study adopted a static group comparison design where third-year PolyU students in the 3-year degree program formed the control group. Third, the measures used in this study possessed good psychometric properties. Finally, the findings are overwhelmingly supportive of the original hypotheses.

In line with the original hypothesis, students in the experimental group performed better than did students in the control group. Compared with students in PolyU 3-year undergraduate degree program, participants in PolyU 4-year undergraduate degree program had higher levels of interpersonal competence (such as empathy and fantasy), and higher levels of intrapersonal development, including resilience, emotional competence, cognitive competence, behavioral competence, self-determination, ethical leadership, life satisfaction, and critical thinking. Besides, students under the 4-year program also showed more effective engagement in university life than did students studying the 3-year program. Specifically, 4-year program students engaged more in collaborative learning, reflective and integrative learning, higher-order learning, and learning activities involving discussion with students with diversified backgrounds. These findings are consistent with the available evaluation findings that the 4-year undergraduate degree program was beneficial to the holistic development of the students [14-18].

Although the findings provided support for the original hypothesis and they were overwhelmingly positive, there are several limitations of the present findings. First, the findings showed that students in the two cohorts were different in their third year (i.e., cross-sectional differences). As cross-sectional comparison can only show differences between the two groups at a particular time point, longitudinal data are needed to give a more complete picture of the differences between the two groups over time. Second, as quota sampling was used, the sample might not be representative of the two groups in the general population. Third, as expected, students in the 3-year program were older than students in the 4-year program because they had one more year of secondary school education. As such, the differences may be explained in terms of age effect. However, this alternative explanation does not make sense because control group students performed poorer than experimental group students, despite the fact that they were older. One possible solution to this problem is to match the two samples further so that there would not be age differences between the two groups. However, by doing this, the sample size would be reduced.

In conclusion, using the static group comparison design, this pioneer study showed that students in the 4-year undergraduate degree program did better than students in the 3-year degree program, which suggests that the GUR component has possible impact on the development of the 4-year degree program students. Nevertheless, one should bear in mind the limitations of the static group comparison design while interpreting the findings.

ACKNOWLEDGMENTS

The preparation for this paper and the GUR evaluation study are financially supported by the Teaching Development Grant of The Hong Kong Polytechnic University. The authorship is equally carried between the first author and the second author. This chapter is based on a paper to be published in the *International Journal of Adolescent Medicine and Health* 2017;29(1).

ABSTRACT

Under the new education reform in Hong Kong, The Hong Kong Polytechnic University (PolyU) has expanded its undergraduate education from three to four years since the 2012-2013 academic year. Along with the transition, the General University Requirements (GUR) has been developed as an integral part on general education of the new four-year undergraduate curriculum of PolyU. The present chapter examined the implementation quality and effectiveness of the GUR in the 2012-2013 academic year based on focus group interviews with teachers. Twenty teachers who taught GUR subjects were interviewed for their perceptions and experiences about the GUR. Results revealed that the teachers generally had positive perceptions of the GUR in terms of its rationales, teaching and learning modes, and implementation quality. GUR subjects were also considered effective in helping students to develop in a holistic manner. The findings suggest that the first-year implementation of the GUR at PolyU was basically successful.

INTRODUCTION

In recent decades, the society of Hong Kong has been experiencing drastic changes. Primarily, Hong Kong has established itself as an emerging knowledge-based economy. In addition, the political and economic blueprint of Hong Kong has been reshaped by its transition from a British colony to a Special Administrative Region of China. Furthermore, the fast development of information technology has transferred Hong Kong people's lives and exposed them to unexpected new domains [1]. Facing these changes, education was deemed vital for developing people with strong character, emotional attributes, adaptability, creativity, and independent learning to underpin Hong Kong's development to be a diverse, democratic, and civilized cosmopolitan city [1]. However, the education system in Hong Kong was criticized for its early narrowing and "streamlining" in students' study [2]. In particular, the three-year undergraduate education under the British system has been criticized for its disciplinary concentration upon students' enrollment and its inadequacy of helping students to develop in a holistic manner. Moreover, pedagogy in both secondary and higher education was criticized for examination-driven, emphasis on passive learning, and inability to provide holistic learning experiences [1].

As a result, there was a strong need to reform the secondary and higher education system of Hong Kong to reinforce general education and promote students' all-round development. In 2000, the Hong Kong Education Commission issued a report named "Learning for Life, Learning through Life: Reform Proposals for the Education System in Hong Kong". The report proposed a comprehensive reform on secondary and higher education in aspects of academic structure, curricula and assessment to foster lifelong learning and all-round education. With regard to higher education, its aim was proposed as:

"to develop students' independent and critical thinking, creativity and ability to learn independently and to explore, in preparation for the mastering of knowledge in a certain discipline; to foster in students an aspiration for self-improvement, a positive attitude towards life and a commitment to their families, their society and their country; and to enhance students' ability to learn, live and work in a diverse social and cross-cultural environment" [1].

To this end, the undergraduate education in Hong Kong was suggested to be reformed from three to four years and to "strengthen general education and multi-disciplinary learning" [1].

Against the above background, the University Grants Committee (UGC) mandated the eight UGC-funded universities in Hong Kong to formally change the structure of their undergraduate education from three to four years in the academic year of 2012-2013. Although the UGC did not directly mandate a formal general education curriculum, it required the new four-year undergraduate curriculum to strike a right balance between the breadth and depth of students' study, and proposed the additional year should "enable students to have more time and space to build a broader knowledge base and a solidier foundation for whole-person development" [1]. The new curriculum was expected to contribute to the development of qualified talents to sustain the development of a knowledge-based economy and fast-changing society in Hong Kong [3]. As a response, all the eight universities officially implemented their new four-year undergraduate programmes in 2012-2013 academic year, with the incorporation of a general education curriculum in each

programme [4]. These universities developed a set of intended learning outcomes for their GE curricula which centered on multidisciplinary knowledge, critical thinking, communication, problem solving, lifelong learning, civic responsibility, morality and global outlook [4, 5]. The GE curricula normally consisted of two components: a core curriculum mandated to all students and a distributional requirements system requiring students to take subjects selectively within several broad knowledge areas [4-6]. Furthermore, a more engaging and active pedagogy and “more authentic forms of assessment” [2] were encouraged in the new GE curricula, which was believed as contributing to “a major transformation of both faculty and student orientations toward the learning process consistent with the stated objectives of the reform” [2].

As one of the eight UGC-funded universities, The Hong Kong Polytechnic University (PolyU) officially launched its new four-year undergraduate curriculum in 2012-2013 academic year. It developed a set of desired graduate attributes for its new curriculum including effective communication, critical thinking, problem solving, lifelong learning, ethical leadership, and professional competence [7]. To cultivate these attributes in students, a unique GE system entitled the General University Requirements (GUR) was developed as a fundamental part of the new four-year curriculum. The GUR consisted of six components [8]: Freshman Seminar (FS, 3 credits), Leadership and Intrapersonal Development (LIPD, 3 credits), Language and Communication Requirements (LCR, 9 credits), Cluster Area Requirements (CAR, 12 credits), Service Learning (SL, 3 credits) and Healthy Lifestyle (HL, non-credit-bearing). Each student who studies in the four-year undergraduate program starting from 2012-2013 academic year is required to complete 30 credits in his or her GUR study which is one fourth of the minimal total credits (120 credits) for graduation. The rationale and purpose of each GUR component are briefly described below:

- FS aims to introduce students to their broad disciplines through offering one mandatory FS subject to all students in each broad discipline.
- LIPD aims to cultivate intrapersonal and interpersonal knowledge and skills that are conducive to effective leadership in students. It consists of two subjects: “Tango! Management Self and Leading Others” (for students in Faculty of Business), and “Tomorrow’s Leaders” (TL) (for students in all other faculties).
- LCR aims to enhance students’ language proficiencies in both English and Chinese. It consists of two sub-components: LCR-Chinese and LCR-English.
- CAR aims to expand students’ intellectual capacity and enquiry methods, and develop students’ reading and writing skills. Each student needs to take at least one subject from each of the four cluster areas of learning: “CAR A–Human Nature, Relations and Development”, “CAR B–Community, Organization and Globalization”, “CAR C–History, Culture and World Views”, and “CAR D–Science, Technology and Environment”. The CAR subjects that each student completed also need to cover three requirements: China Studies Requirements, English Writing and Reading Requirements (EW/ER), and Chinese Writing and Reading Requirements (CW/CR).
- SL aims to develop the awareness and competence to serve others in students through requiring each student to take one subject with significant service component.

- HL aims to help students acquire knowledge and skills for maintaining a healthy lifestyle through requiring each student to take a non-credit-bearing subject in HL.

Most GUR subjects have incorporated a more active and engaging pedagogy in their teaching and learning strategies, including group project, hands-on workshop, field work and real case demonstration. More authentic forms of assessments like individual/group project and peer assessment were also incorporated to effectively evaluate students' meaningful application of essential knowledge [9]. In 2012-2013 academic year, 107 GUR subjects were offered to all first-year students enrolled in the four-year undergraduate programme.

While the reform in higher education was rigorous in Hong Kong, little evaluation research has been conducted. With reference to PolyU, there is a need to examine whether the GUR ran smoothly and how effective it was in promoting students' all-round development. To this end, a five-year comprehensive evaluation project was conducted since 2012-2013 academic year. Different evaluation components were incorporated in the project, including objective outcome evaluation based on a longitudinal survey on students' changes under the new four-year curriculum and the GUR and on Collegiate Learning Assessment Plus (CLA+), subjective outcome evaluation based on secondary data analyses of the PolyU Student Feedback Questionnaire (SFQ), qualitative evaluation based on yearly student and teacher focus groups, and longitudinal case study. Teacher focus group is one component of qualitative evaluation, aiming to investigate teachers' views on the GUR with reference to its teaching and learning, implementation, and perceived benefits and challenges.

Qualitative evaluation was incorporated in the current evaluation project for several reasons. First, as commonly used methods in evaluation research, qualitative methods help researchers explore in-depth human experiences and perspectives, which could not be obtained by quantitative methods [10-12]. Second, qualitative evaluation is characterized by its intensity, subtlety, depth and detail in data collection [13, 14], which was contributed by the nature of qualitative data collection that "not constrained by predetermined categories of analysis" [13]. Third, qualitative evaluation helps researchers identify "the factors that contribute to successful or unsuccessful delivery" [11]. It also helps explore the program outcomes and how these outcomes are brought into being.

Focus group interview is a widely used qualitative method which collects data through interviewing a group of people on their perceptions, experiences, and attitudes toward a defined topic [15-17]. It was adopted as a method in qualitative evaluation in this study for the following reasons. First, focus group is more efficient than observation and individual interview in terms of the time and energy required [16]. Second, focus group is useful for investigating participants' attitudes and perspectives which are hard to be obtained from observations [16]. Third, compared with individual interview, focus group provides an opportunity for researchers to identify the similarities and differences between participants' views through group discussion so that further explorations can be carried out [16, 18]. Furthermore, focus group is advantageous for gaining "richer and more well-thought-out ideas"[19] and "providing some in-the-moment triangulation as interviewee elaborate, explain, and correct information as it is provided" [20]. Focus group method has been widely used in educational settings for educational planning and assessment [21-24]. In the specific context of Hong Kong, focus group method was used to evaluate subjects promoting holistic development and leadership in university students [25, 26].

In this study, focus group method was adopted to explore the views of subject teachers on the GUR with reference to its teaching and learning, implementation, perceived benefits and challenges in the first-year implementation. Teachers teaching GUR subjects are important stakeholders of the GUR because they are directly involved in activities of class teaching and obtain first-hand information of course delivery and students' changes. Comparing to students, teachers would look at the issues from an adult, teacher, and professional perspective. As teachers are directly involved in the development of GUR subjects, and are more familiar with the policy of the GUR, their understanding would offer an alternative perspective different from those of other stakeholders such as students. Teachers' views could also be balanced by and integrated with students' views to gain a more comprehensive understanding of the implementation status of the GUR. Against this background, the present study attempted to investigate the implementation and effectiveness of the GUR at PolyU in its' first-year implementation (2012-2013 academic year) based on focus group interviews with teachers. As a qualitative evaluation research, the principles suggested by Shek, Tang and Han [27] were adhered to as far as possible. A general qualitative orientation was adopted in this study.

OUR STUDY

The participants were teachers involved in the teaching of GUR subjects in 2012-2013 academic year. These teachers were recruited in May of 2013 through the nomination of program leaders and invitation of key teachers in different GUR components. In late May and early June, four teacher focus groups were formed and conducted, with each focus group corresponding to one specific GUR area. The four focus groups were: TL, CAR, LCR-English and LCR-Chinese. A total of 20 teachers participated in the focus groups. The numbers of participants in each focus group were: TL ($n = 6$), CAR ($n = 4$), LCR-English ($n = 4$), LCR-Chinese ($n = 6$). There was no focus group interview being conducted for SL, HL and FS. As SL subjects were not offered to Year 1 students in Semester 1 and Semester 2, there was no need to collect data for this area. For FS, as the senior management met with teachers of FS at the end of 2012-2013 academic year, this component was not assessed. Since HL subject refers to a systematically stepwise training within two years which starts from lecture to fitness and sports skill training, there were only lectures of health and sports knowledge offered but no substantial training conducted in the first academic year. Therefore, the focus group of HL was also not conducted.

The length of the focus group interviews ranged from one to two hours. The whole process of each focus group was audio-recorded. A focus group protocol was developed by the research team to guide the interview. The protocol was comprised of four major categories of questions including: (a) teachers' understanding and perceived significance of the GUR; (b) teachers' views on the teaching and learning of GUR subjects; (c) teachers' observed and perceived changes from students in studying GUR subjects, and (d) teachers' perceptions of the challenges in the implementation of the GUR.

All the focus group records were transcribed into full texts. All the transcripts were imported in NVivo Software (Version 10) for analyses. Each transcript was carefully read for at least twice and coded in the software into different categories/themes based on the

transcript itself and the focus group protocol. After the initial coding, all the codes were read again for further organization. Inter-rater reliability on the coding was also calculated. A research assistant who was not involved in the coding process re-coded 20 randomly selected narratives without knowing the original codes generated. The inter-rater agreement percentage calculated on the generated themes from the coding was 90%.

OUR FINDING

At the very beginning of the focus group interviews, teachers were asked to express their understanding and perceived significance of the GUR. Basically, the majority of teachers indicated their basic understanding of and agreement with the rationale of the GUR. Some selected narratives were provided below to show teachers' understanding:

"We agree with the idea of the GUR which tries to broaden students' horizons. GUR actually has a broad coverage. It includes broadening subjects, subjects related to students' health and students' leadership development, and so on. This is good and this is what we agree with."

"To my understanding, GUR subjects are to provide students with a general education in addition to their development in their major studies. These are general topics for all the students regardless of their major studies. I agree with the idea of the GUR because it is very important to students' all-round development."

A few teachers' elaboration was richer and more profound than the original rationale of the GUR, which reflected their in-depth understanding of the philosophy of general education. For example, a teacher in the focus group of CAR said:

"Based on my understanding, GE (GUR) has three aims. The first [aim] is to train students' critical thinking and communication skills, and other generic transferable skills. The second aim is to develop in students a basic and overall understanding of human, society and the world, and capacity to make value judgments. The third aim is to develop in students a sense of responsibility based on their understanding of the critical issues in the world."

With reference to teachers' perceived significance of the GUR, majority of teachers perceived the GUR as important and valuable for the development of students beyond their major studies. For example, in the focus group of CAR, another teacher said:

"I perceive these [GUR] subjects as very important because they would not focus on one discipline but provide students with opportunities to learn knowledge in other disciplines and promote students' interdisciplinary development. This is very important for students because they are usually absorbed in the study in their own disciplines. Nevertheless, when they enter into the society, they would face a very broad world. Therefore, the GUR provides them with opportunities to learn different aspects of the world and to develop in multiple ways."

Teachers' Perceptions of the Teaching and Learning of GUR Subjects

Teachers in focus groups were asked to express their views on the teaching and learning (T&L) of the GUR subjects. Teachers' perceptions were generally highly positive. They perceived the adoption of active and engaging teaching and learning methods in their subjects as effective in promoting students' active engagement in learning and their development of

important generic skills. For example, teachers whose subjects involving group work expressed that group work greatly facilitated peer learning and peer interaction, and developed students' interpersonal skills. In the focus group of CAR, one teacher said:

"I think they (students) quite like group work. ...we have created some activities in my subject. Students enjoyed it a lot. ... At the beginning of this term, I grouped students into four different groups and students complained you know 'I want to be a group with Catherine when I am doing this'. But at the end, they were grateful that they were not with their friends because they learn[ed] so much better with some other people. And they can actually exchange ideas better."

A few teachers mentioned that at the very beginning, group work might not be very appealing to students but be more challenging to them. However, after completing group work tasks, students treasured their learning experiences very much since the process provided them with authentic opportunities to interact with their peers. One teacher in the focus group of TL expressed:

"The group project and presentation must not be called 'appealing' to the students. But it is a very important task for them because they need to present their group tasks in front of all the students in the class. But for many groups of students in my class, it was in this moment that they felt this subject had impact on them very much....One interesting aspect is that through students' final reflections, I found that they treasured their learning in group work and presentation very much. And through group work and presentation, they were experiencing the process of interaction with others, learning to do group projects better, and learning to listen to others better."

Teachers also remarked that the experiential learning component in their GUR subjects offered students profound learning experiences through learning by doing and from real-life experience. This T&L mode was regarded as highly conducive to the development of students' problem solving ability. In the focus group of CAR, a teacher who taught one subject on dealing with disasters said:

"I asked students to go to community to do assessment. So they came to know a lot about their surroundings because in the past they did not pay much attention to. I was asking them to take note of everything that was not perfect and they took pictures and then they would have to offer me how to improve their surroundings so that you know we reduce the risks of disasters. ...We have also had big exhibitions that our students could participate by going into the exhibition and they could ask people questions why these are important and how am I going to use this. They learned in a real life environment and I think that will make things different for them and by doing so they picked up cues from the environment. You know each point would be a learning point for them and I think that is important. You don't actually need to open a book and read in order to learn because learning from life experiences is one way of learning so that sharpens students' observational skills and also they learned how to improvise things."

Other engaging teaching and learning methods have also gained teachers' positive comments, such as case demonstration and visualized methods. Teachers commented that visualized methods such as video-playing were much welcomed by students and engaged students in learning because they helped to demonstrate the abstract subject contents in a vivid approach to facilitate students' understanding.

Meanwhile, teachers perceived that some traditional methods such as mere lecturing in a large lecture hall were less conducive to students' active learning and students' interaction with their peers and teachers, and were less appealing to students.

Teachers' Perceived Changes from Students after Studying GUR Subjects

Teachers in focus groups were also asked to describe their perceived changes in the students after taking their GUR subjects. The responses were very positive. Majority of teachers responded that they perceived positive changes in their students after attending their classes. The most obviously perceived change was improvement of students' communication skills in both Chinese and English. Teachers in the focus group of LCR-Chinese expressed that, after fourteen weeks' teaching, they observed obvious improvement in their students' discussion and expression skills. For example, one teacher said:

"Students do have changes. For example, in the discussion session in my first class, I found that many students' discussion was very 'standardized' or 'mechanical'. They would prepare in advance who speaks first and who second. This was very obvious. However, in the later classes, I saw their improvements. Some students began to try to make summaries or conclusions of others' points. Some would try to lead the discussion back to the topic if the discussion was going off the track. In the final stage, some students' progress was very obvious, especially in their listening and inquiry skills."

Teachers in the focus groups of LCR-English and CAR also perceived improvement of their students' English written communication skills through the training of academic writing in these subjects. For example, teachers in the focus group of LCR-English expressed that their students' writing skills were improved through the process of integrating and criticizing different sources in their writing. Teachers in the focus group of CAR expressed that CAR subjects with English reading and writing requirements greatly facilitated the development of students' English writing skills through a collaborative effort of CAR subject teachers and teachers in English Language Centre (ELC) in instructing and supervising students' writing tasks. This benefit of the GUR could be illustrated by the following selected narratives:

"At the very beginning, students felt their [LCR-English] subjects could be just like other English subjects in their secondary school and they could handle them quite easily. Then later on by having done the course, they realized that these subjects were not exactly the same, because that kind of depth of research and the ability to produce or put all the ideas together and to show that they are able to critique... All these elements are something that students really appreciated."

"Because my subject had reading and writing requirement, students needed to see teachers in ELC. Here I especially want to express my gratitude to ELC teachers for their support, inspiration, and help to my students. During my teaching of this subject, comparing to the same year students' writing assignments in other subjects, I found that the assignments of my students were much easier for marking. For example, in the past I usually needed to read students' writings for several times to understand what they were saying. Now I don't find this barrier anymore."

Another change from students perceived by teachers was the deepening of students' understanding of interpersonal and intrapersonal attributes after students had studied the TL subjects. Viewed by teachers in the focus group of TL, students were changing from not perceiving the relevance and importance of the leadership theories to increasingly being aware of the value and importance of the intrapersonal and interpersonal attributes to their lives. For example, one teacher in the focus group of TL expressed:

"I feel that they (students) changed gradually from not knowing what the subject was teaching in the first semester to thinking these [interpersonal and intrapersonal] attributes important and needed to be learned in the second semester. ... I think that the impact [of the subject] is that they gradually understood what roles these attributes would play in their lives."

TL teachers also perceived the deepening of students' understanding of "leadership" after attending the TL courses. They said that many students perceived leadership as just "an inborn trait to lead others" or had other misunderstandings such as "I don't want to become a leadership so I don't think it is necessary for me to take this subject", etc. at the very beginning of the classes. However, many of these students changed their mind-sets at the later stage of the subject. For example, some students realized that leadership also meant "self-leadership" and "to take responsibility for one's own life". One teacher said in the focus group:

"One point I want to highlight is that students' understanding of the concept of leadership has changed a lot. At the very beginning of the class, many students thought this subject had no relationship with them because they thought many leaders were 'inborn'. Some students thought they could never become a leader because they did not have the inborn traits of a leader. However, after completing this subject, many students thought that actually every person could become a leader. Most importantly, they knew that they should 'take responsibility for their life' which meant they knew the importance of self-leadership."

Furthermore, some teachers indicated the development of students' self-reflection and self-awareness through writing reflective journals. Students' critical thinking and problem solving skills were also perceived as improved through knowledge study, experiential learning, and writing assignments in different GUR subjects.

Although positive changes from students were perceived, some teachers cautioned that the development of some attributes such as critical thinking and ethical leadership might need a longer time and might not be obviously perceived by teachers. Nevertheless, teachers believed that their subjects would serve as a foundation in facilitating students' development in these important attributes, as was said by one teacher in the focus group of TL:

"Actually I think growth needs time. That means some students might possibly be enlightened by the subject after ten years later. But that doesn't matter. I hope the impact is 'sowing the seeds' and actually these seeds were not firstly sowed by us. Some people have sowed them in an earlier stage. What we do is to continue to give water and nutrition to them to keep them growing."

Teachers' Perceived Challenges in the Implementation of the GUR

In the focus groups, teachers were also asked to express their perceived challenges in the implementation of the GUR. One major challenge noted by the teachers was CAR subject registration. Teachers in the focus group of CAR noted that many students encountered difficulties in registering CAR subjects because students in different departments were assigned different timeslots to register CAR subjects. Those whose departments were assigned a later timeslot would find few places left in the registration system for them. One teacher in School of Nursing who also taught CAR subjects expressed this "inequality" of CAR subject registration system:

"At the very beginning, some of the students from my department indicated that they would really like to join my subject (a CAR subject). The problem is none of them could get on to it because within the first hour [of subject registration], all the places were gone. Because they arrange different departments to register [CAR subjects] in different time zones, my students usually have a later time zone because they think my students have five years [of undergraduate programme] and they could do it (CAR) later on. But later on, my student will need to go to hospital [to do clinical placement]."

Another challenge noted by the teachers was some teachers' heavier workload in teaching and marking students' assignments. A few teachers in focus groups indicated that they felt stressful in teaching large classes and marking hundred pieces of students' writing assignments. These teachers expressed expectations for more manpower assistance in their teaching and paper marking tasks.

DISCUSSION

This study attempted to evaluate the implementation and effectiveness of the GUR at PolyU in its first-year implementation based on teachers' perspectives collected from focus group interviews. This study has several strengths. First, in view of the paucity of evaluation studies of the new four-year curriculum in Hong Kong, this is a pioneer study. Second, teachers were recruited in this study because we believed that teachers were major stakeholder of the study. This practice is in line with the standards of evaluation in the major evaluation societies on evaluation [28]. Third, as there are few evaluation studies on general education programs in the Chinese context, this is an additional unique feature of this study.

The present findings suggested the GUR subjects were successfully and smoothly implemented and they contributed to the development of desired graduate attributes in undergraduate students at PolyU. As key stakeholders of the GUR implementation, teachers generally understood and agreed with the rationale of the GUR. They perceived the GUR as important for students' development. Teachers' agreement with the rationale of the GUR is vital to the successful implementation and continuing development of the GUR. Reform on GE was not only a curricular but also a cultural change [29] and one critical obstacle to it is the apathetic or "not buy-in" attitudes of academic staff towards the new GE curriculum [30]. For example, research showed that faculty' resistance to the reform of general education could result in the turning down of reform proposals, drawn out of the reform process, and the unachievable reform goals [31, 32]. Therefore, development of shared educational values and philosophy is a key to the implementation of GE [33], and significant effort should be made to ensure teachers' internalization of rationale of GE [34].

Teachers' views also indicated a basic alignment of the GUR with the desired graduate attributes of PolyU. The factors that contributed most to this alignment were active and engaging T&L methods that were widely adopted in different GUR components, including group project, field trip, case demonstration and visual methods, etc. The adoption of an active pedagogy facilitated students' understanding and digestion of subject contents, engaged students in learning, and promoted students' development in some important attributes such as communication, interpersonal relationship, self-reflection, critical thinking and problem solving. As shown in the literature, the group work and experiential learning could provide students with profound experiences in learning, develop in them important competencies, and connect their learning to practices [35-37]. The recent reform on GE also showed a changed focus from content to teaching modes and methods [38], and a transition from traditional to more engaging and student-centered T&L methods such as group project, case study, experiential learning, etc. [39]. These methods were shown to have stimulated students in learning and to be more conducive to students' all-round development than some traditional methods [40-42].

Finally, challenges were identified from the present findings, which was important for improving the implementation of the GUR. Students' difficulty in CAR subject registration indicated the limitations of CAR subject registration system and the inadequacy of CAR subjects on offer, which might be a risk for future successful implementation of the GUR. In view of these findings, the registration system was enhanced and refined in 2013-2014 academic year.

The present findings are basically in line with the findings of student focus groups conducted by Shek et al. [43] on the implementation of GUR in 2012-2013 academic year. The focus group findings showed that students gave highly positive comments on the active and engaging teaching and learning mode of the GUR, and perceived the GUR as beneficial to their development in all-round way in terms of the important attributes of communication, problem solving, lifelong learning and leadership. With particular focus on TL, the findings are consistent with the findings of the quantitative evaluation conducted by Shek and Leung [44], Shek and Ma [45], Shek and Yu [46] which indicated that the TL subject was beneficial to the holistic development of the students.

Several limitations of the study should be noted. First, although focus group interview is good at collecting constructed ideas and perspectives from different participants, its conclusion is limited when making generalization or representativeness to a larger population [47]. Second, since teacher is the only one kind of stakeholders, their views might not represent the views of other stakeholders such as students or administrators. The experiences of other stakeholders need to be voiced. Furthermore, the current findings need to be triangulated by findings from other stakeholders. For example, a combination of teachers' views with those of students could help gain a better understanding of the "merits" and "flaws" of the GUR and of students' development. Furthermore, to gain a more comprehensive understanding of the implementation of the GUR, findings based on other evaluation methods need to be incorporated, such as objective outcome evaluation and longitudinal case studies on students. Despite the above-mentioned limitations, the current study provides evidence on the effectiveness of the GUR as a unique GE curriculum in promoting all-round development in undergraduate students in PolyU. In conjunction with the findings of other evaluation methods, the GUR at PolyU can be regarded as successful in promoting the holistic development of the students. Given the limited literature on the evaluation of GE in Hong Kong, the present study could be considered an important contribution to the field.

ABSTRACT

Using teachers’ focus group interviews (n = 40), this study examined the impact of the General University Requirements (GUR) implemented at The Hong Kong Polytechnic University (PolyU). Results showed that teachers were generally satisfied with the GUR subjects and its implementation in its second year. Teachers regarded the design of GUR subjects was good and the students generally welcomed the subjects. Interactive teaching and learning methods adopted in GUR subjects such as fieldwork, hands-on project, and team debate were highly appreciated by the respondents. Teachers also reflected that the GUR had promoted the intrapersonal and interpersonal development of the students. However, several challenges were also reported by teachers,

* Corresponding Author’s Email: daniel.shek@polyu.edu.hk.

including the difficulty level of Freshman Seminar subjects and lack of interaction in some GUR subjects, which suggested directions for further improvements.

INTRODUCTION

Program effectiveness can be assessed by different methods and the view of program implementers is one of the key areas for evaluation. There are several reasons why program evaluation should include the view of program implementers. First, since program implementers are important stakeholders in program development, their ideas should be identified and taken into account [1-3]. Second, from a practical perspective, a more holistic view about the program effect can be obtained from program implementers and thereby improves the quality of program implementation. Specifically, program implementers can provide opinions regarding the feedback from the program participants. At the same time, program workers would gain a sense of equality and respect when their voices are heard, which may further promote their work enthusiasm and engagement. Third, program implementers play a particular role in providing their opinions concerning the activities being implemented and suggestions on how the program can be improved. For instance, in adolescent prevention programs, it is common to interview the program workers (e.g., social workers and teachers) regarding their perceptions of the program design, objectives, and rationales [4, 5]. In such contexts, program implementers are believed to have more relevant experiences in making professional judgment about the quality of the program.

With reference to school/university-based programs, teachers are essential implementers and their perceptions about the program provide important information on the effectiveness of the program implementation [6-8]. First, as teachers are the primary deliverers of the program, their feelings, comments, and suggestions are crucial for quality program implementation in school/university settings [5]. As noted by Flannery and Torquati [9], “teachers who are not satisfied with a program are less likely to use the program materials, regardless of whether their principal or district administration is supportive of the program” [9]. Second, teachers with professional training and experience can usually view the program in a deep and professional way and thus are in a good position to assess the effectiveness of the program. Third, teachers who are directly engaged in class teaching can gain valuable information (i.e., students’ changes and teaching problems) which program managers, developers, and researchers could not obtain directly. Therefore, in evaluating university-based programs, it is necessary to take into account the views of teachers. Despite the merits of teachers’ views on school/university-based program, evaluation research based on teachers’ views is grossly inadequate in different Chinese contexts. In this study, we examined the effectiveness of a university-based general education program in Hong Kong from the perspectives of teachers.

At The Hong Kong Polytechnic University (PolyU), a new general education program entitled “General University Requirements (GUR)” has been developed and implemented since 2012/13 as an integral part of the four-year undergraduate curriculum. The purposes of the GUR are to promote the development of five core attributes in PolyU undergraduate students, including effective communication, innovative problem solving, critical thinking, ethical leadership, and lifelong learning. There are six areas in GUR as follows:

- 1) *Freshman Seminar (FS)*: Introduce student to the professional world of a broad discipline, cultivate higher order thinking skills, encourage entrepreneurship and learn to engage in self-directed and autonomous study.
- 2) *Language and Communication Requirements (LCR)*: Help students to develop language competence for academic and professional needs in both Chinese and English.
- 3) *Leadership and Intra-Personal Development (LIPD)*: Help students to develop self-awareness and acquire interpersonal and self-reflection skills essential for an effective leader.
- 4) *Cluster Area Requirements (CAR)*: Expand intellectual capacity beyond disciplinary domain.
- 5) *Service-Learning (SL)*: Apply the knowledge and skills from university learning to meet community needs.
- 6) *Healthy Lifestyle (HL)*: Acquire the basic knowledge and skills to maintain a healthy lifestyle and quality of life.

To evaluate the effectiveness of GUR, a five-year longitudinal project has been conducted since the inception of the new four-year undergraduate curriculum in 2012/2013 academic year. The project adopts a mixed-method design including the collection of qualitative and quantitative data. Qualitative methods include document analyses and focus group interviews with different stakeholders (e.g., teachers and students). Quantitative methods include objective outcome evaluation addressing student-level developmental indicators and subjective outcome evaluation on students' feedback on GUR subjects.

Using such a mixed-method design, previous evaluation research on initial implementation of GUR demonstrated favorable findings. For example, in a study based on student focus groups ($n = 62$), it was found that participants generally had positive perceptions of GUR subjects, the teachers, and the benefits of the subjects in 2012/2013 [10]. Another study based on teacher focus groups ($n = 20$) in the same academic year revealed similar findings that the subject contents, teaching quality, and the effectiveness of GUR subjects were perceived in a positive manner by the teachers [11]. A more recent study based on student feedback questionnaire showed that students generally held positive perceptions of GUR subjects in terms of their learning experiences and the quality of staff teaching in 2012/2013 [12]. These findings consistently suggest that the initial implementation of the GUR was successful.

Despite the success of the GUR in its first-year implementation, it is unknown whether the program implementation in its second year would also be smooth and effective. In 2013/2014 academic year, the GUR implementation had two new features. First, there were modifications in the curricula of a few GUR subjects. In particular, LCR subjects' arrangement and policies were refined in 2013/2014. For example, in 2012/2013, students with low levels of English and Chinese language proficiency were required to take remedial courses to enhance their basic skills before they could take advanced courses. However, such remedial courses were cancelled in 2013/14 based on the feedback of students and teachers. Another example is Freshman Seminars. With the experience in first year, the content and delivery mode of Freshman Seminars were fine-tuned in 2013/14 school year. Second, the number of students enrolled in 2013/2014 increased largely ($n = 32,339$) as compared to 2012/13 academic year ($n = 21,080$). Thus, class size, teaching strategies, and resources were

refined accordingly. It is imperative to find out whether these factors may affect GUR implementation.

Against this background, the present study attempted to examine teachers’ views on GUR subjects and its implementation in 2013/2014 via focus groups approach. Specifically, teachers who taught GUR subjects in this academic year were invited to participate in focus group interviews regarding their views on the contents, teaching and learning methods, perceived benefits on students, as well as perceived challenges of the GUR subjects they taught. It is expected that findings of the present study would constitute an important addition to literature about the evaluation and improvement of general education program in university contexts.

THE FOCUS GROUP

A total of 40 teachers who taught GUR subjects in 2013/14 participated in the focus groups. These teachers were mostly nominated by leaders of the relevant subjects. Seven teacher focus groups were formed, with each group corresponding to one specific GUR area including FS, CAR, SL, LCR-Chinese, LCR-English, LIPD-“Tango! Managing Self and Leading Others” (Tango!), and LIPD-“Tomorrow’s Leaders” (TL). The number of participants in each focus group ranged from three to nine and the related information is presented in Table 1. One teacher who taught in two GUR areas was invited to participate in two focus groups.

Table 1. Number of participants in each session of teacher focus group interviews

Teacher Focus Group Interviews	No. of Participants
Session 1 (LCR-Chinese)	9
Session 2 (FS)	4
Session 3 (CAR)	6
Session 4 (SL)	6
Session 5 (LCR-English)	6
Session 6 (Tango!)	3
Session 7 (TL)	7
Total	40

Note. One teacher taught in two different GUR areas were invited to participate in the focus groups in these two areas. Therefore, the sum of numbers of participants in each focus group was 41 and the actual total number of the participants was 40. “Tango!” and “TL” belong to LIPD component.

All focus groups were conducted at the end of the second semester of 2013/2014 academic year. For each interview session, one researcher was present served as the moderator hosting the whole interview. The moderators were all academic staffs in the project with rich experience in qualitative research. The length of the interviews ranged from one to two hours. The group interviews in all six focus groups were audio-recorded. The process of one focus group was recorded by taking notes since one participant refused the audio-recording. All six audio records were transcribed into full texts. Each transcription text was further checked by a research assistant of the project and a student helper with basic research training to ensure accuracy and consistency.

A teacher focus group protocol was developed by the research team to guide the interviews with teachers. The protocol included the following basic categories: (a) teachers' views on the contents of the GUR subjects, (b) teachers' views on teaching and learning of the GUR subjects, (c) teachers' perceived benefits of the GUR subjects on students, (d) teachers' views on the evaluation system of the GUR subjects, and (e) major challenges perceived by teachers in GUR implementation.

The six transcripts based on audio tapes and one written summary for one focus group interview were imported into NVivo Software (Version 10) for coding, which coded the raw data into different themes and categories based on both the transcription text and the interview protocol. Specifically, by using NVivo software, a researcher coded each transcript for at least twice. After the initial coding, all the codes were further read and organized by the researcher. During this process, only one researcher was involved. Doubtful codes were resolved through discussion amongst the researchers. The inter-rater reliability was also examined. After the initial coding, another researcher who did not know the initial codes recoded 20 randomly selected narratives. The inter-rater agreement percentage on the selected narratives was 90%. Common themes and categories were generated in five aspects: contents, teaching and learning, perceived benefits, evaluation system, and major challenges in GUR implementation.

WHAT WE FOUND

At the very beginning, teachers were asked to express their views on the contents of the GUR subjects they taught. The majority of the teachers perceived the subject contents as inspirational and highly welcomed by students. For example, a teacher in the focus group of LCR-English subjects said:

"In the first chapter, we started to talk about styles, and they (students) have to start to understand better, and know what kind of words can be used in academic writing and what kind of words cannot be used. And they (students) actually seemed to be quite interested in this one; they felt like, 'oh, I've never thought about this one...you know, like these (words) [students showing to me] should not be used in academic writing.'"

Besides, most teachers perceived that the GUR subject content was beneficial, interesting, rich, and concrete since they were closely related to students' practices and real life issues. Several related narratives were provided below:

"I think the design of course is not only for text examination, but also for promoting students' capability for dealing with difficulties in life. We asked students to design Chinese version of leaflets and advertising narrations. The students liked it and thought the skills were very useful in the commercial society." (One teacher in LCR-Chinese)

"I am collecting students' reflective journal these days. By reading their writings, I feel the course is really interesting. Many students treat the course very positively. Because they think the course really let them broaden their horizon and attracts them. Science students think the content talking about culture in the course is very interesting." (One teacher in CAR)

"I think this is very important. ... I don't know how others teach leadership. Within the community, students in the leadership courses typically play with 'paper tower exercise'. That is traditional teaching. They (teachers) don't teach some concrete knowledge. These (the contents in TL subjects) are really some research-based evidence. ... I think the content was very rich and could also be transferred to different disciplines." (One teacher in TL)

On the other hand, teachers in some subjects, especially FS subjects, expressed concerns on their subject content. They were worried that some FS subjects were a bit too difficult for freshmen to study. Teachers also perceived the contents of a few GUR subjects as not directly related to students' own disciplines which had probably reduced the students' learning motivation. Meanwhile, promising suggestions were also raised by teachers accordingly to address these issues. Two teachers in the focus group of FS subjects said, respectively:

"FS seminars in APSS required students to finish the project work assignment. I think the scope of assignment, particularly quantitative data analysis, might exceed students' ability at the time of the subject offered. It might be very hard for freshmen to obtain such knowledge."

"Ur, our students (in FS subjects) complained: 'Why am I learning things that I don't need to use at work?' I think students might need to find motivation to learn from other's stream as some might express contempt towards streams other than their own. I suggest maybe making lecture captivating, multimedia, and interesting could be a way out to resolve the students' disinterest in exposure to broad discipline in their own field."

Teachers' Views on Teaching and Learning of GUR

Teachers were also asked to verbalize their views on teaching and learning of the GUR subjects. Teachers generally held positive perceptions. They perceived that the adopted teaching and learning methods can help students develop self-learning ability, facilitate students' understanding of the subject content, promote students' engagement in learning, as well as provide students with profound learning experiences. Among different teaching and learning methods, interactive approaches based on experiential learning were highly appreciated by the teachers. Specifically, the majority of the teachers consistently noted that field work was effective and greatly favored by students. For example, two teachers in the focus groups of CAR and SL illustrated, respectively:

"I think field work is very useful for our students' learning. For example, many students in my class (CAR) told me they treasured the home visit opportunity very much. I observed they did not know how to get along with older people at first. They were very nervous and had no confidence. They did not know how to communicate with the older people. In the end of field work project, they could easily talk with the older people and actively asked what they can help. Through getting along with old persons, I think students can truly feel and understand what the outside world looks like and really hope they can do something to help people in need."

"I have two groups of students in my class (SL). One group of students went to Sichuan (a province in China) to experience life there. I felt the experience (going to Sichuan) greatly impacted them (students). Now, they have started to learn to think about self and life, think about ideal and reality, and think about what they can do for the society."

In addition to field work, teachers perceived that hands-on project in assignment as another effective and welcomed method. For example, in the focus group of CAR, one teacher expressed:

"I feel students really like and devote to complete the video assignment. The quality of the assignment is quite good. I am surprised they spent much time on doing the thing, especially in examination period, but everyone submitted it. They were also happy and enjoyable in the process of critiquing videos."

A number of teachers also expressed that team debate was favored and welcomed by students. They perceived that this method promoted students' cognitive ability. For example, one teacher in focus group of LCR said:

"For Persuasive Communication, um, I think the students enjoy the debate part of the course. The course ends with the teams' debate. I find that there are big intellectual challenges for them (students) because they have to predict what the other team is going to say and prepare their arguments against it, etc. and think on their feet and reply to the arguments. Um..."

Apart from the aforementioned teaching and learning strategies, considerable teachers also mentioned that in-class group discussion was very beneficial to students' active learning. Through interacting with others, group discussion provided students profound learning experiences, such as collaborative learning, critical thinking, and communication skills, etc. Moreover, a number of teachers commented that utilizing visual aids such as video-demonstration was highly favoured by students and successfully engaged students in learning. On the other hand, teachers reflected a few sessions of GUR subjects delivered by renowned speakers were not well-received by students due to a lack of interactions. Improvements on the designs of these subjects are needed to further motivate students' learning and participation.

Teachers' Perceived Benefits of the GUR

When being asked about the benefits of GUR subjects, teachers expressed very positive views. They considered the benefits of GUR subjects comprehensive which covered different areas. Teachers observed several direct positive changes in students after taking GUR subjects. The first was students' improved communication competence in both oral and written skills, though such changes were usually not immediate. Several selected narratives were provided below to show teachers' positive comments:

"In fact, the course (TL) provides a platform for students to meet different people who might come from different countries or be with different backgrounds. They (students) need to overcome language obstacle and egocentrism, and self-disclose to talk with different people. After taking the subject, many students told me that it (the course) was a very good learning experience. I think effective communication is reached." (One teacher in TL)

"In my opinion, the subject (SL) is very useful for communication. Because students would meet different people and deal with different real-life situations and problems. Of course, they (students) do not only learn verbal communication, but learn how to use different ways to creatively communicate with other." (One teacher in SL)

"The improvement is not immediate, it takes 2 to 6 credits of LCR to... and they are still learning how to... you can see the difference from when they entered university at the very beginning... more like secondary school students' writing style. When they finished the subjects, they are more on their way to be able to write academic essays. Sometimes, I would like to use 'turn bad into good' to describe many students' achievement in academic writing in end of course. I am very happy to see this." (One teacher in LCR)

Teachers perceived the second most obvious improvement among students was their competence in ethical leadership. Teachers reflected that after attending GUR subjects, students' capacities of self-leadership and reflection, empathy to people in need, and social responsibilities were developed. Several selected narratives were provided below to show teachers' perspectives:

"I strongly agree students learn self-reflection and self-management by taking the subject (TL). Some students once felt it's difficult for them to wake up in the morning. Even washing face and coming to school to attend morning classes were very difficult things. Now, they have self-reflection on these life styles and some of them started to make plans and write diary. I think this is a very important improvement." (One teacher in TL)

"I feel a lot of students take many things for granted most of time. After taking the subject (of CAR), they realize happiness is not taken for granted. They also realize their behaviors influence others and should usually consider from others' angle." (One teacher in CAR)

"They (students) wrote something about visiting older people in their reflective journal. From their writing, I find they start to have social responsibility. They want to help older people, but they feel their ability is limited. But I think at least they think about how to help them (the older people). The subjects (in SL) offered such opportunities for them (students). I think the subjects are very useful for my students." (One teacher in SL)

The third positive change described by teachers was the improvement in students' problem solving ability as shown in their group projects. For example, one teacher in the focus group of SL stated:

"When I talked to students about group assignment, I feel they are quite daunted by it at the very beginning. But then that's why I say that they really grew in confidence and improve ability in solving problems. Because in order to complete the task, they have to think how can they possibly do for this assignment, and how do they find someone to interview, how do they interview them, etc. Then, you see, they figured it out in the end."

A few teachers also mentioned that GUR subjects promoted students' capacities of critical thinking by encouraging students to think from different perspectives and asking them to write persuasive essays and to do comparison. For example, two teachers described as below:

"In EUS (a course in advanced LCR-English subject), they (students) cannot simply describe a view; they actually have to either defend it or criticize it. It requires slightly higher cognitive skills." (One teacher in LCR-English)

"In this course, we did a lot of critical comparisons. We asked students to read texts and literature, as well as, um, like movies, or adapted plays, and we asked them to do a comparison of the two. Then, they really have to use, you know, use their brains to talk about the literary creation and the ways by which things are handled in the two different media." (Another teacher in LCR-English)

Furthermore, a few teachers indicated that students' capacities of lifelong learning, global outlook, and resilience were also developed as reflected in their group work, presentation, and reflective writing in GUR subjects.

Teachers' Views on the Evaluation System of GUR

Regarding views on the evaluation system of GUR subjects, teachers generally had positive comments on the current assessment mechanism. For example, teachers in the focus group of TL expressed that the evaluation system is quite effective because it employed comprehensive evaluative methods to examine both objective and subjective outcomes of the subject. For example, there are objective outcome evaluation which measures students' development in different positive attributes before and after taking the subject; qualitative evaluation in which students are asked to use three metaphors to describe their general impression about the subjects, and student feedback questionnaires which gauge their subject views on learning experiences and teachers' effectiveness in this subject. Such an evaluation

system provides the teachers with important information in understanding the effectiveness of the subject from different aspects. In particular, teachers of TL mentioned that a post-lecture evaluation effectively helped them understand students' comments and suggestions after each lecture. Based on students' feedbacks, teachers can make immediate improvements in the following classes. For example, one teacher in the focus group of TL said:

"Actually, I think post-lecture evaluation really helped me to know my teaching effectiveness. Particularly from open-ended questions, I can receive their (students') ideas and feedbacks. Then I can respond to those students quickly in the next lecture. They (students) are also impressed that what they wrote can be really paid attention to by the teacher. They became more willing and active to share their opinions. I think this is a positive circle."

Besides, teachers in LCR-Chinese subjects perceived that the frequent formal meetings among subject teachers and written reviews on the evaluation of the subjects effectively helped them further improve the subjects, as shared by one teacher as below:

"From teachers' perspective, I think the evaluation system is very exquisite. We had regular meetings for each GUR component subject. We discussed these courses and wrote reflective reviews. In meeting, every teacher reported what were problems of their courses; what were students' and teachers' feedbacks? For example, there is one subject of LCR-Chinese. We had many meetings to discuss how we could teach better. We did many revisions about teaching design. As a result, I find students much liked and enjoyed the course. I am also satisfied with the quality of the course. I think meeting is very useful."

Teachers' Perceived Challenges in GUR Implementation

Near the end of each focus group interview, teachers were invited to describe their perceived challenges in delivering the GUR subjects. Several issues arose that deserve attention. First, students' instrumental orientation and indifferent attitude towards general education potentially undermined their active participation and engagement in GUR subjects. Teachers believed that it would take time to change students' mindset and improve their learning attitudes. For example, one teacher in focus group of LCR-Chinese said:

"I think the most difficult thing is that they (students) asked what this (course) has to do with me. Why do they need take the course? For example, science students asked why I need to take Chinese subject. It is really hard to explain to them. ...But they would understand the importance. I think it needs time."

Second, some teachers expressed that marking writing assignments and group work in large classes brought them heavy workload, as one teacher in the focus group of "Tango!" claimed:

"Group and individual assessment in large classes in FS and LIPD in fact, is regarded as one of the major challenge in the evaluation. For example, we have only 3 or 4 teachers. But we have a lot of students. It's really a hassle when we have such a large group presenting and we are trying to, you know, trying to give a mark to every group in terms of the performance and see how everybody got on board. It is really huge work."

Third, it was observed that Mainland students generally had more difficulties in LCR-English subjects than local students, as most Mainland students were not well trained in oral and written English skills in their secondary schools. For example, one teacher in the focus group of LCR-English said:

"I think the students from Mainland China come here in a stream line according to their university entrance examination. It may not be a very good predictor of their language proficiency. Their speaking and writing productive skills are really really not trained. In Mainland China, basic speaking is not tested in their university entrance examination, so lots of Mainland students come here, rather than get into EUS, um... there are very good students but you can see them struggling..."

Besides, teachers teaching SL subjects expressed that the SL trips could not get funds from the Finance Office of the University in advance. Teachers and students needed to pay everything by themselves first and the following reimbursement procedure was very complicated, which may negatively influence students' learning motivation and engagement.

DISCUSSION

This paper presents the qualitative evaluation findings of the General University Requirements (GUR) at The Hong Kong Polytechnic University in 2013/2014 academic year based on data collected from teachers' focus groups. The findings indicated that the GUR was evaluated positively by teachers in its second year implementation. Primarily, the GUR subject content was perceived by teachers as beneficial and interesting. According to Ranaweera [13] and Gibbs et al. [14], the content of general education in universities should not only meet diverse and changing needs of students and society, but also arouse teachers' interest and enthusiasm and form their positive attitude toward general education. Teachers' positive attitude and involvement would positively and significantly impact the effectiveness of general education curriculum delivery. Teachers' general positive perceptions on the GUR subject content revealed in the present study may further motivate them to teach the subjects with passion and thus further promote the effectiveness of the program. Meanwhile, some concerns expressed by teachers on the level of difficulty in FS subjects, such as statistical analyses, must be addressed. Lecture contents of these subjects should be modified to better address the needs of first-year university students.

Several teaching and learning methods adopted in GUR subjects were highly praised by teachers in focus groups, including field work, hands-on project, and team debate. These methods are common in their interactive nature and the use of experiential learning. Students learned effectively by discussing, reflecting on, and applying the theoretical knowledge in solving real problems. These interactive learning approaches were also welcomed by students and successfully facilitated students' active participation in these subjects. In the present study, teachers reflected that students' positive feedbacks further encouraged them to adopt more interactive/participative methods based on experiential learning in their GUR classes. This would result in more favorable learning outcomes.

On the other hand, teachers noted that lectures lacking interactions were not well-received by students even they were delivered by famous speakers. Lucas [15] suggested that teachers may feel reluctant to use interactive methods due to their teacher-centered pedagogical philosophy. However, there has been an increasing consensus that students' active learning is much more effective than passively receiving the instructions by teachers, along with which the mode of education has been changed from teacher-centered to learner-centered [16, 17]. The present finding provides further support to the benefits of learner-centered interactive methods in teaching general education subjects.

Teachers generally perceived that GUR subjects have brought comprehensive benefits to students. This finding is consistent with previous findings based on teachers' and students' focus groups in 2012/2013 academic year [11, 12]. At the intrapersonal level, the teachers observed that GUR subjects strengthened students' self-reflection, self-regulation, critical thinking, lifelong learning, and problem solving skills. On the interpersonal level, teachers reported that the subjects enhanced students' oral and written communication competence, ethical leadership, particularly social responsibility and empathy. These findings indicate that the GUR program has effectively promoted students' development in the five desired university student attributes and facilitated their all-round development.

With reference to the evaluation system of different GUR subjects, teachers generally considered the current mechanism effective and useful. For example, post-lecture evaluation and formal regular meetings were perceived by subject teachers as helpful for them to maintain and improve the quality of subject implementation in a timely manner. The findings also echo previous reports showing effective evaluation mechanism of a subject could serve as a useful strategy that enables teachers to quickly understand their teaching effectiveness [18-20]. Before subjective and objective outcomes on the effectiveness of GUR program can be observed, the evaluation system of each subject would provide immediate information on the subjects which is important for teachers to make timely adjustment on the subjects.

Despite the aforementioned positive findings, several challenges expressed by teachers should be noted, which implies directions for further improvements of the GUR implementation. First, relatively low learning motivation toward GUR subjects in some students were noted by several teachers, which could potentially affect the learning outcomes of the GUR [21]. To tackle the problem, it is important to help students understand the rationale of implementing general education and the importance of whole-person development for university students. Related GUR orientation workshops can be conducted upon students' enrollment to convey these messages. Second, although most teachers held positive views on the implementation of GUR subjects, a few teachers responded that marking written assignment and group projects in large classes created heavy workload. This may be related to the increased number of students enrolled in 2013/2014 as compared to 2012/2013, which has led to larger class sizes particularly in GUR subjects. The University may consider how to reduce the workload of these teachers, such as hiring more tutors to share the work. Third, it was noted that Mainland students showed difficulties in their first-year English learning. Special assistance in improving first-year Mainland students' English proficiency may be needed. In addition to the English Department, different organizations in the University may also provide workshops to help Mainland students better adapt to the new learning environment. Fourth, teachers in SL subjects complained about the complicated funding application and reimbursement procedure. More supportive services shall be provided to staff and students by the University to facilitate a smooth and efficient implementation of SL subjects.

The current study has several strengths. First, congruent with previous research findings [10, 20, 22], the present study provides further evidence for the effectiveness of university general education curriculum in promoting student whole-person development based on teachers' perspectives. Second, the study affirms an overall successful and smooth implementation of the GUR at The Hong Kong Polytechnic University, a pioneering general education project in universities in Hong Kong. Third, the study demonstrates the strengths of obtaining teachers' views in program evaluation. The personal feelings and experiences

shared by the teachers provided deep insights on different aspects of the program implementation and outcomes, which can guide further improvement of the program in the future and triangulate findings obtained from other evaluation research.

Nevertheless, several limitations of the study shall be acknowledged. First, although most focus groups had an ideal number of participants in the present study [23], two groups (“Tango!” and “FS”) only had three or four participants. The small sample sizes may influence the representativeness of the information collected. Future studies could try to recruit more teachers for these two groups to obtain more diversified views of teachers. Second, while focus groups have many methodological benefits in program evaluation, they cannot be used in isolation due to some inherent disadvantages. For example, respondents may feel peer pressure to give similar answers to the interview questions, and the moderator’s skills may affect the responses from the participants. Therefore, other research methods such as quantitative evaluation based on a more representative sample and in-depth individual interviews focusing on individual teachers’ perspectives shall be conducted to further evaluate the implementation process and effectiveness of the GUR. Third, while the present study investigated the perspectives of teachers who are important stakeholders of the GUR program, other stakeholders’ opinions shall not be overlooked. Future research should examine the views of students, administrative staff, and other stakeholders on the implementation of the GUR to gain a more comprehensive picture.

ACKNOWLEDGMENTS

The preparation for this paper and the GUR evaluation study are financially supported by the Teaching Development Grant of The Hong Kong Polytechnic University. The authorship is carried equally by the first author and second author. This chapter is based on a paper to be published in the *International Journal of Adolescent Medicine and Health*.

ABSTRACT

The General University Requirements (GUR) is the core general education component of the new four-year undergraduate curriculum at The Hong Kong Polytechnic University (PolyU) commencing from 2012/13 academic year. The major objective of the GUR is to widen students' horizons and promote their holistic development in their undergraduate years. To evaluate the perceived effectiveness of the GUR in its second year implementation, 18 focus group interviews (n = 74 students) were conducted in 2013/14 academic year. Findings showed that subjects under the GUR framework were overall welcomed by students for the well-designed subject contents, dedicated teaching staff, and collaborative and experiential learning methods. Students perceived that the GUR was beneficial to their development ineffective communication, critical thinking, problem solving, lifelong learning, and ethical leadership. Some challenges encountered by students were noted to further revamp the GUR curriculum in the future.

INTRODUCTION

The Hong Kong Polytechnic University (PolyU) is one of the eight public universities in Hong Kong under the funding of the University Grants Committee (UGC). In 2012/13 academic year, PolyU formally transformed its undergraduate programme from three years to four years. A core general education structure named “General University Requirements” (GUR) was developed as a foundational part of the new four-year curriculum. In combining with students’ disciplinary studies, the GUR at PolyU aims to nurture students with a broad knowledge base, and capacities of effective communication, critical thinking, innovative problem solving, lifelong learning and ethical leadership, defined by PolyU as the five desired graduate attributes under the new four-year curriculum. Credits assigned to GUR subjects account for one quarter of the total credits of university study required for graduation. GUR has become a major vehicle to achieve PolyU’s new mission to deliver a more “balanced and well-rounded education” [1].

The curriculum reform at PolyU as well as in other universities in Hong Kong was shaped by the drastic social changes. Hong Kong’s economy has been altered from a manufacture-based to a service-based one. Nowadays, “98% of Hong Kong’s GDP is based on services” [2], which raises challenges for nurturing high quality manpower with flexibility and generic skills. The globalized knowledge economy, rapid outdated of knowledge, and increased societal instability in Hong Kong also confronted tertiary education with the need to cultivate graduates with adaptability, self-directed learning, effective communication, intrapersonal attributes, and knowledge transferable skills [3, 4]. Furthermore, the change of Hong Kong from a British colony to a special administrative region of China raised demands for social leaders who could actively engage in the construction of Hong Kong’s new political identity and civil society [2]. Despite the above challenges, government and business sectors complained that local university graduates lacked creativity and innovative ability although they were good at examination skills [2]. These graduates were also regarded as not adept at “making thoughtful decisions in the workplace” [3]. The Hong Kong education system is criticized for being examination-driven, giving insufficient attention to lifelong learning, and lacking “comprehensive learning experiences” [4].

Specifically, the three-year British-style higher education system was blamed for early streamlining students’ learning [4] and early vocationalization [2]. This system was incompatible with the international trend stressing a broadened learning in higher education [4]. To address these challenges and problems, a systematic and comprehensive education reform was initiated after the handover to Hong Kong in 1997. Starting from 2006/07 academic year, senior secondary education in Hong Kong has been changed into a 3-year structure in order to provide a coherent and diversified learning experience to secondary school students and to equip students with a solid foundation for lifelong learning [4]. Along with the senior secondary education reform, all eight public universities in Hong Kong formally extended their undergraduate education programmes from three years to four years starting from 2012/13 academic year. Students under the new four-year undergraduate programme are provided with more room for their whole-person development. In the new undergraduate education framework, each university developed its respective general education curriculum as an embedded component. General education, a curricular tradition in

American higher education, was revitalized in Hong Kong to make higher education to be “the inspiration for institutional and pedagogical transformation” [5].

The GUR at PolyU has several unique features. First, the GUR curriculum is comprised of six distinct components, with each having its characteristic design and specific learning outcomes, as briefed below:

- Freshman Seminar (FS) (3 credits). FS is a mandatory subject offered to students from each broad discipline in their first year of study.
- Leadership & Intrapersonal Development (LIPD) (3 credits). LIPD aims to introduce theories/concepts of leadership to students to prepare them to be leaders in their profession.
- Language and Communication Requirements (LCR) (9 credits). LCR aims to develop competences of effective communication in both Chinese and English in students. LCR comprises two components: LCR-English (6 credits) and LCR-Chinese (3 credits).
- Cluster Area Requirements (CAR) (12 credits). CAR aims to expand intellectual capacity and develop multiple disciplinary perspectives of students. It comprises four cluster areas of learning. Each student needs to take at least one subject from each area. Also, the subjects taken by each student need to cover three requirements: “China Studies”, “English Writing and Reading” and “Chinese Writing and Reading”.
- Service Learning (SL) (3 credits). Each student needs to take a subject with a significant service component to apply academic knowledge into practices, and develop sense of civic responsibility.
- Healthy Lifestyle (HL) (non-credit-bearing). HL aims to develop knowledge and skills for maintaining a healthy lifestyle.

Second, the GUR stresses students’ active and participative learning as reflected in its interactive pedagogy. For example, Tomorrow’s Leaders (TL), one LIPD subject offered to around 2,000 PolyU freshmen every year, adopts a pedagogy combining lectures, experiential classroom activities, group project presentation, and written assignments to promote students’ reflective, experiential and collaborative learning [6].

Third, strong administrative mechanisms were established to ensure a quality implementation of the GUR [7]. Special assistants to Vice President were appointed for the GUR development and quality assurance. A university-wide Task Force was formed to facilitate the GUR development and implementation. Subjects in different components were piloted and refined before their formal implementation.

Last but not least, various evaluative studies have been conducted to evaluate the GUR implementation since its launch [8-10]. Multiple evaluation methods were adopted in this longitudinal research, including objective and subjective outcome evaluation, qualitative evaluation based on open-ended questions, longitudinal case study, and focus groups with different stakeholders [11].

Wright and Hendershott [12] suggested that the evaluation in one time point might give “partial truths”. Although the evaluative findings in the first year of GUR implementation are encouraging, it is necessary to investigate the effectiveness and implementation quality of the GUR in subsequent years. The present paper reports findings obtained from student focus

groups in 2013/14 academic year, i.e., the second year of implementation. Focus group, defined by Krueger and Casey [13], was “a carefully planned series of discussions designed to obtain perceptions on a defined area of interest in a permissive, nonthreatening environment.” It collects rich data on participants’ perceptions in a more cost-effective way [13], and helps achieve a deeper understanding of the topic during group interaction [14]. In this paper, students’ views on the GUR were examined via focus groups.

OUR STUDENTS

The participants were 74 Year Two students enrolled in the new four-year undergraduate curriculum in 2012/13 academic year at PolyU. At the end of the first semester of 2013/14 academic year, 320 students were randomly selected from all Year Two students, with 40 students being selected from each faculty/school. A total of 18 student focus groups were conducted before the end of the 2013/14 academic year. All the focus groups were faculty/school-based. The numbers of focus groups for each faculty/school were: FAST (n = 2), FB (n = 2), FCE (n = 3), FENG (n = 2), FH (n = 2), FHSS (n = 2), SD (n = 2), and SHTM (n = 3). The number of participants in each group ranged from two to six (Table 1). There were two sessions (one in FCE and one in FHSS) with only two participants. For these two sessions, four students had formerly agreed to participate while only two finally attended as the absentees were engaged with some emergency issues. The length of the interviews ranged from one hour to one and a half hours. For each interview, one researcher was presented to serve as the moderator. The whole process of each focus group was audio-recorded with students’ consents.

Table 1. Number of participants in each session of student focus group interviews

Student Focus Group Interviews	No. of Participants
Session 1 (FB)	6
Session 2 (SD)	3
Session 3 (FENG)	4
Session 4 (FCE)	3
Session 5 (SHTM)	3
Session 6 (FAST)	4
Session 7 (FENG)	4
Session 8 (FHSS)	4
Session 9 (FAST)	6
Session 10 (SD)	5
Session 11 (FH)	3
Session 12 (SHTM)	6
Session 13 (FHSS)	2
Session 14 (SHTM)	5
Session 15 (FCE)	2
Session 16 (FB)	5
Session 17 (FCE)	4
Session 18 (FH)	5
Total	74

Note. FB: Faculty of Business. SD: School of Design. FENG: Faculty of Engineering. FCE: Faculty of Construction and Environment. SHTM: School of Hotel and Tourism Management. FAST: Faculty of Applied Science and Textiles. FHSS: Faculty of Health and Social Sciences. FH: Faculty of Humanities.

A focus group protocol developed by the research team in 2012/13 academic year was revised and used in the present study to guide the interview. The protocol is comprised of four major categories of questions: [1] students' general impression about the GUR; [2] students' views on the GUR subjects (including contents and teaching); [3] students' perceived benefits of the GUR; and [4] students' comments about the implementation of the GUR.

All the records of the 18 focus groups were transcribed by student helpers into full texts. To ensure the accuracy and consistency of the transcription, four researchers further checked the 18 transcripts and made minor amendments. The transcripts were then imported into NVivo Software (Version 10) for coding and analyses. Each text was coded for at least twice. The common themes and categories were initially generated based on coding of the texts. After the initial coding, the common themes/categories were further read, organized and confirmed by one researcher. To test the inter-rater reliability, another researcher who did not know the original coding recoded 20 randomly selected narratives from the transcripts. The agreement percentage of the recoding and the original coding was 85%.

FINDINGS

Five major themes emerged from the data, including 1) well-designed subject contents, 2) caring and devoted teachers, 3) collaborative and experiential learning-based pedagogy, 4) benefits of the GUR subjects, and 5) smooth implementation. These themes are further elaborated below.

Well-Designed Subject Contents

The GUR was appreciated by students for its "well-designed" course structure and contents. Students in focus groups expressed that this design had provided them with valuable opportunities to learn their interested subjects. In fact, many students were eager to learn and understand the world beyond their own disciplines and thus they appreciated rich content of the well-designed curriculum of GUR subjects which successfully evoked their inner learning motivation. One merit of the CAR component summarized by students was that many interesting materials in different knowledge areas were incorporated in the subject content and students were given "some degree of freedom" to choose their favorite subjects to fulfill their personal interests:

I like to study history. However, in my high school, I had no opportunity to study arts subjects as I enrolled in the science stream. The University helped me fulfill my desire; I have studied [the subject on] the History of Hong Kong [in CAR].

Students also highly praised the course design of service learning subjects. They appreciated the reasonable proportion of class-teaching and service practices, and the matching of knowledge taught in the classroom with direct service activities. Some SL subjects were perceived by students as having concise, clear, and logical content:

I think my service learning subject is very good. The subject is related to doing service in Shanghai. I think the proportion of the theory and practice parts [in the subject] is perfect. For the theory part, we had three lectures and each lecture taught us three things. The content was very concise and insightful. It is because this concise and insightful content that we could easily link the knowledge with our service practices.

One concern noted by students was the design and level of difficulty of subjects in CAR-D (“Science, Technology and Environment”). Students without science background (e.g., majoring in social sciences and humanities disciplines) expressed that the contents of CAR-D subjects were too advanced and specialized for them, which made them feel frustrated:

I haven’t studied science subjects in my high school. Then [in the university] I selected one subject [in CAR-D] the title of which looked interesting to me; it was about electronic music. Later on, however, I found myself “fell into an ambush” since the subject offered very “professional” science knowledge to students, such as those of “waves in physics”.

On the other hand, another group of students from Faculty of Humanities viewed their selected CAR-D subjects as well-designed with interesting contents. These subjects enabled the students to appreciate the beauty of science:

I am now taking a subject in CAR-D named “Science behind Crime Scene Investigation (CSI)”. ... So far I think this subject is very good, because it actually depends on how the professor designs the course and its purpose. ... The professor uses very simple ways to teach us how to discern in a crime scene where several holes exited in a window hit by a hammer which hole was hit first.

Caring and Devoted Teachers

A number of students noted that they loved their GUR subjects because their subject teachers were dedicated and enthusiastic. The teachers’ passion, knowledge, and personal characters demonstrated in teaching altogether provided students with profound and unforgettable learning experiences:

One of the CAR-C subjects I studied was taught by a very brilliant and passionate lecturer... I think through this subject it is the first time that I felt having learned something. ... She was very brilliant! She spoke a lot of interesting things. We never felt the class boring. She also had a lot of interactions with us during the class. Although the class was held in a very big lecture hall, there were a lot of students attending the class every week. Almost all seats were occupied [in each class].

Students were also impressed by the warmth and care given by their teachers. For example, a few students expressed that their teachers showed great concerns on their learning experiences and always tried to make improvement based on students’ feedbacks. Some students mentioned that their teachers could remember their names even in the first few weeks, which made them feeling being respected:

I have very good and deep impression of the teacher of my service learning subject. ... Our teacher was very dedicated to attend each class in different times to oversee and provide assistance to us. So I think my teacher is very good.

Furthermore, a few students complimented their subject teachers on their detailed guidance in their learning process which greatly facilitated their learning:

[In Service Learning] ... Our teacher gave us very clear criteria and guidance and provided us with the good and bad examples for making the storybooks. Then in the following service, we could really use these books to teach.

Meanwhile, students believed that less engaged and dedicated teachers had negative impact on students' interests in the subjects. In fact, as noted by several students, their participation in GUR subjects largely depended on the "lecturer". For subjects with "half-hearted" teachers, students said that the number of students attending the lectures decreased significantly week by week:

One student: In certain subjects, the lecturers did not want to teach and engage us. Then we had no interests and did not want to learn in a serious manner. The lecturers also felt very hard teaching us.

Another student: It really depends on the lecturer...

The first student: It did! One lecture I encountered is like that. In his first class, the lecture hall was almost full; however, in his second and later classes, the lecture hall was almost empty...

Collaborative and Experiential Learning-Based Pedagogy

GUR subjects were also praised by students for the interactive pedagogy that focused on collaborative learning and experiential learning, including group work, field trip, hands-on workshop, real case demonstration, multimedia methods, etc. Students gave very positive comments to these teaching and learning methods. One beneficial outcome of collaborative learning raised by students was their broadened social network. Students felt "happy" to "know people from other disciplines" through group work. Different group projects also promoted students' development in communication and leadership skills, just as a student from Mainland China expressed in the focus group:

The GUR subjects [in PolyU], such as CAR subjects, would arrange group work [to us]. Different students, no matter from Mainland [China] or Hong Kong or no matter from one discipline or multiple disciplines, would have more chances of communicating with each other; learning many things from one another; knowing how to communicate and discuss with others. I think this [mode of learning] is very meaningful.

A number of students used "interesting", "attractive", and "happy" to describe the experiential learning components in their GUR subjects such as field trip, laboratory work, in-class experiment, etc. Students perceived that the experiential learning helped them better comprehend the knowledge and apply the knowledge in their daily lives:

I think some CAR subjects were intriguing. For example, I have studied one on food science which taught food quality and smell. ... The most favorable part was that it had a lab for us to DIY food, e.g., making molecular ice-creams. I think this format could really make students learn more things ... as well as develop a better understanding about the knowledge which could be used in their daily lives.

Furthermore, students gave highly positive comments to their service learning experiences. They perceived service learning as happy, hands-on, and "meaningful". Some students shared that they gained multicultural learning experiences in their field trip and were provided with opportunities to "really help people". Such experiences successfully fulfilled students' inner desire to serve and help others.

I think service learning will teach you the reality ... My service learning subject was related to the community tourism. You could really see what the clients want, and you planned for catering their needs, e.g., doing a real conference.

Benefits of the GUR Subjects

During the focus group discussions, benefits of the GUR subjects constantly emerged. Two general categories of benefits were identified by the participants, i.e., broadened learning experience and personal development in different desired graduate attributes defined by PolyU. First, the majority of students perceived that their GUR study broadened their knowledge base, horizons and experiences. Different GUR components such as CAR, SL, and HL exposed students to different knowledge domains beyond their disciplines. Through GUR study, students gained more opportunities to interact and communicate with their peers from other disciplines, which enriched their views about the world. Several narratives were provided below to illustrate these benefits:

In studying CAR I have gained exposure to different subjects in other disciplines, although the learning experience was painful sometimes. For example, in semester one I have studied one subject on China's reform and opening-up. Although I hate to study history all along, I think this subject offered me some different perspectives and helped me understand more about China.

My most impressive experience was to visit and talk with people lived in the "rippled room". This experience really let me know more. For example, I asked them where they go in their daily life and how they apply the subsidy, etc. Then I came to understand the huge gap between the rich and the poor, and how a poorest person could be.

In my SL subject, I went to Cambodia. Since we depended on the local students as our language translators, we had more communication with them and learned their cultural and historical background, as well as the local life.

Second, students generally viewed their GUR study as conducive to their personal development in different areas particularly the five desired graduate attributes. Students expressed that GUR study helped them develop oral and written communication skills. The group projects in many GUR subjects effectively trained students in communication with their peers from different disciplines with distinctive thinking styles. The experiences gained in group presentation also greatly enhanced students' confidence and ability in public speaking:

I think I have developed more confidence through doing a variety of tasks such as group works and individual projects [in GUR study]. In my first several group projects, I often felt that I had less contribution to the projects, and did not dare to express my views. Then, after experiencing so many group projects, I feel that the group project is not so scary, and I am able to express what I am thinking now.

Students also perceived the CAR subjects with reading and writing requirements as much helpful in improving their skills of academic writing in English. Students appreciated the close collaboration between CAR subject teacher and teachers from English Language Center (ELC), by which students obtained continuous guidance from ELC teachers while completing their writing assignments in CAR subjects:

I think that the CAR subject with [English] reading and writing requirements that I enrolled in was very useful. The subject required us to write an essay. In the middle of the semester, we met with the tutor (ELC teachers) and he discussed with us the problems in our essays. I felt this part very useful.

GUR study also promoted students' motivation and skills for lifelong learning. As mentioned, students commonly perceived that CAR subjects had aroused their interests in learning knowledge of other disciplines. The writing tasks in certain GUR subjects also trained students' independent learning such as literature search and review on particular topics.

Some students mentioned that their leadership competences were promoted through their GUR study, such as team-building skills, habit of self-reflection, and a strong sense of responsibility. All these were important ingredients in ethical leadership:

[After studying the GUR subjects,] my abilities in thinking and reflection were improved. I really did more self-reflections on some ethical issues, and on my own performance and cooperation with others in doing things.

Smooth Implementation

Most students expressed that their GUR study went smoothly. However, a small number of students had relatively slow progress in GUR study which was mainly due to personal issues. Meanwhile, students also shared their concerns on the course registration system for the CAR and HL subjects. Some students commented that it became more difficult for them to select their preferred CAR and HL subjects in 2013/14 academic year than the previous year because in this year, there were two cohorts of students compete for the limited quota of each subject. For some popular subjects, the competition was fierce:

I think the registration of HL subjects was a very troublesome issue. I am not able to register HL subjects. So troublesome!

DISCUSSION

This study investigated students' views on the perceived implementation and effectiveness of the General University Requirement at The Hong Kong Polytechnic University in 2013/14 academic year through focus group interviews. The findings indicated an overall success of the GUR in its second year of implementation. Students perceived the GUR as effective in promoting their holistic development and the implementation of GUR was smooth.

Several observations could be highlighted. First, students viewed the content of the GUR curriculum as well-designed and interesting. While LCR, LIPD, and FS basically adopt the "core requirement" mode in which students have to take the subjects in a compulsory manner, CAR, SL, and HL have more "distributional requirements" which give students more freedom to select their own preferred subjects [15]. Such design well balanced the "prescription" of the University and students' "personal interests" in general education and provided students with comprehensive learning experiences.

Second, students had very positive perceptions about the teachers of GUR subjects. In particular, the teachers were described as “caring” and “dedicated”. The knowledge, attitude and passion in these teachers greatly motivated students’ active learning in GUR study. This finding is in line with the literature which suggests that teacher plays a key role in high quality general education [16-18]. For example, Gaff [19] argued that “courses, even well-designed ones, are insufficient without effective teachers who can stimulate students and assist them in learning.” In Wright and Hendershott’s [12] study, students’ satisfaction about a course was found closely related to the enthusiasm of the course teacher demonstrated in teaching. Apart from this, Noddings [20] also stressed that “caring is the very bedrock of all successful education.” It is believed that caring teachers are able to establish close bonds with their students by believing in and affirming their students’ efforts, potential and talents, place their students at the center of the educational process, and engage their students in learning, which is “essential for learning to be fun, meaningful, and enduring” [21]. Given the fact that most research on the role of teachers in effective teaching and learning was based on primary or secondary school settings and few studies had been conducted in the context of university general education, the present finding could be regarded as an interesting contribution to the literature.

Third, students favored the interactive pedagogy adopted in GUR subjects based on collaborative learning and experiential learning. Researchers pointed out that the adoption of pedagogy emphasizing active learning had become one of the most important trends in general education reform in American universities [22-24]. There are literature supporting the significant impact of such pedagogy on students’ learning outcomes [25, 26] through promoting students’ direct interaction with subject contents [27], and placing “the onus of learning on learners” [28]. This could not be achieved by traditional lecture method which focused on knowledge instilling and memorization [28]. The present findings further suggest that the interactive pedagogy was well-received by students. Since the goal of general education is to develop students’ qualities, attitudes, and generic capacities instead of static knowledge, interactive pedagogy seems to be vital for the success of general education programs and should be promoted in teaching GUR subjects. Even in classes with large size where lecturing is inevitable [29, 30], teachers may try to adopt more active teaching methods such as small-group work, class discussion, short writing activity, or student presentations during the lecture sessions [26, 30].

Fourth, students perceived the GUR as beneficial to their development, especially in broadening their learning experiences and fostering their personal qualities in the five desired graduate attributes. For example, CAR subjects were perceived as having greatly improved students’ skills in the areas of effective communication, critical thinking and lifelong learning. SL subjects challenged students to be problem-solvers and ethical leaders when providing services in the community. This finding also echoed previous findings based on different evaluative studies that suggested the effectiveness of the GUR in promoting university students’ holistic development.

In conclusion, based on students’ views shared in focus group interviews, the implementation of GUR in 2013-14 academic year can be regarded as smooth and successful. The findings also provide further evidence for the effectiveness of the GUR in developing important qualities and competences in students at PolyU. Meanwhile, there are several limitations of this study. First, although students are important stakeholders of the GUR program, the viewpoints of other stakeholders such as teachers need to be collected to provide

a more comprehensive picture about the effectiveness and implementation of the GUR as well as to triangulate students' views [28]. Second, while the method of focus group interview is advantageous in collecting rich and in-depth data, generalization of the findings should proceed in caution. Quantitative evaluation methods based on a larger sample of students shall be used to further evaluate the GUR. Despite the limitations, due to the limited evaluation research on the new general education and the new four-year undergraduate curricula in Hong Kong, the present study constitutes an important contribution to the field.

ACKNOWLEDGMENTS

ABSTRACT

To promote leadership and intrapersonal development in university students, a subject entitled "Tomorrow's Leaders" was developed and offered at The Hong Kong Polytechnic University. To assess the perceived effectiveness of this subject, 647 students completed the Student Feedback Questionnaire. Results showed that the feedback questionnaire had very good psychometric properties, including internal consistency reliability and construct validity. Regarding students' views of the subject, results showed that students generally had good evaluation of the content of the subject, teaching quality, and perceived benefits of the subject. The present findings have implications for the teaching of general education regarding leadership development.

INTRODUCTION

In the global world of today, the economy in many places such as Hong Kong has gradually transformed from product orientation to service orientation. Product-oriented economy emphasizes logistics and products, and thus often requires obedience of followers to leaders' demands [1, 2]. In contrast, service-oriented economy emphasizes on services as well as the benefits of all participating parties in the economic exchange. Several leadership concepts, such as Servant Leadership [3, 4] and Service Leadership [5], have been put forward to address the important leadership issues in the service-oriented economy. These leadership concepts emphasize the importance of shared leadership and leadership qualities involving a variety of interpersonal and intrapersonal competences [4, 5]. To cultivate qualified graduates who will become the pillar of tomorrow's society, universities have an urgent need to develop validated program/subject that can foster leadership qualities in students.

Globalization also brings other changes to the society, which requires the development of new thinking and new skills. For example, the economy in China has been growing sharply and the Chinese market has become increasingly important for business in the world. In such context, more and more Hong Kong people may work for mainland China's market and they will encounter the challenges of mastering Mandarin Chinese language [6]. Facing such changes, life-long learning should be emphasized for university students where they need to enhance self-learning along with the acquisition of more knowledge [6].

In the context of Hong Kong, Shek pointed out that because of limited tertiary education resources admission to Government funded universities is highly competitive. As a result, students and schools tend to pay great attention to the academic performance of the students [6]. As higher education in Hong Kong tends to be utilitarian with a strong emphasis on employment after graduation, sense of purpose and self-fulfilment are largely neglected. As a result, although the development of intellectual competence may be rather successful in Hong Kong, other competences of university graduates such as social, emotional, and interpersonal competences are largely ignored by both educators and students themselves [6]. Over-emphasis on examinations and the related demands also create much stress for the students. Indeed, several studies suggested that there were psychological problems in Hong Kong students. For instance, Wong, Cheung, Chan, Ma, and Tang [7] found that above 20% university students displayed depression problems and over 40% university students displayed anxiety symptoms. Besides, around 10% students at The Hong Kong Polytechnic University showed psychological problems deserving further attention [8].

It is important to promote university students' holistic development, especially their psychosocial competences [6]. A few scholars argued that courses that facilitate students' character development are pivotal to their life [9, 10]. Building on the above-mentioned background, a subject entitled "Tomorrow's Leaders" (TL) was offered to the 4-year students in 2012/13 academic year at The Hong Kong Polytechnic University. The main goal of TL was to promote student all-round development. Specifically, the subject attempted to "enable students to learn and integrate theories and research of basic personal qualities (particularly intrapersonal and interpersonal qualities) of effective leaders; to train students to develop and reflect on their intrapersonal and interpersonal qualities, and to promote the development of

an active pursuit of knowledge on personal qualities in leadership amongst students” [11, p. 108].

TL was designed as a credit-bearing course typically offered to Year 1 students based on the rationale that the subject is beneficial for the personal development of the students in their four-year university life. Various teaching approaches were used to enhance student learning experiences in this course, including lectures, experiential learning session, group project presentation, and written assignment [6]. Before this course was officially offered in 2012/13 school year, it was piloted in four classes ($n = 268$) in the 2010/12 academic years to understand the implementation process and the effectiveness of this course on students’ development [12]. Multiple evaluation strategies including process evaluation, objective evaluation, subjective outcome evaluation, and qualitative evaluation were conducted. Results generally showed that students were interested in this course and they also evaluated the course content, course design, and the teaching quality in a positive manner [13-15]. Moreover, students perceived that the course facilitated student general development (especially their development in psychosocial competences) and increased their potential to be qualified future leaders [16-18].

In most universities in Hong Kong, student feedback survey is commonly conducted at the end of each semester to evaluate the effectiveness of different subjects. Such evaluation by students (also known as client satisfaction approach or subjective outcome evaluation) is important for keeping teaching staff as well as course and curriculum designers informed of students’ perception of effectiveness of the course and qualities of teaching. This can help teachers to be aware of whether a course is well received by students as well as how to improve this course. Although some scholars questioned that subjective outcome evaluation may not truly reflect the situation [19-21], a number of studies did demonstrate that clients’ satisfaction of a program was associated with their objective changes [22-24].

At PolyU, student feedback survey has been adopted as a way to evaluate different subjects for a long time [25]. Due to the changed undergraduate curriculum in 2012/13 academic year, several rounds of revisions were made on the student feedback questionnaire. To evaluate the subject “Tomorrow’s Leaders”, the Student Feedback Questionnaire (SFQ) was further revised to make the items be more aligned with the characteristics of the subject and its specific learning outcomes [26]. This custom version of SFQ for TL has been used since 2012/13 academic year to provide student subject outcome evaluation on this course. In the first semester of 2012/13, results showed that students had positive perceptions about the subject in terms of their perceived learning experiences, achievement of learning objectives, and teaching of the staff members [27]. While the findings based on the revised SFQ provided important evidence for the effectiveness of TL from students’ perspectives, the psychometric properties of the questionnaire were not thoroughly examined. Although previous researchers have reported good reliability evidence of this questionnaire, its construct validity has not been investigated.

The current study had two main purposes. The first purpose was to investigate the psychometric properties of the SFQ by examining its internal consistency reliability and construct validity. The second purpose was to further investigate students’ evaluations of the subject “Tomorrow’s Leaders” (TL) offered in the second semester of 2012/13 academic year in terms of both the subject and the teaching staff.

CONTACT WITH ALL THE STUDENTS

One week before the completion of the course, an email was sent by the Educational Development Centre (EDC) of PolyU to all students who took TL inviting them to voluntarily complete the SFQ online for this subject by the week after the course was finished. In the second semester of 2012/13 academic year, 1,002 students were enrolled in this subject, among whom 393 males and 254 females ($n = 647$) completed the SFQ online. The students were all in the first year of their university study. Students' answers were automatically saved by the online system. The data were preliminarily processed by EDC and all personal information (such as faculty, student ID, etc.) was removed from the dataset before it was used for research purposes to ensure the anonymity and confidentiality.

The SFQ for TL was revised by the Research Team of the subject based on an original version developed by the Educational Development Centre of The Hong Kong Polytechnic University [28]. The revised questionnaire has two sections. The first section is about students' perceptions about the subject which includes three scales: perceived learning experience (4 items), achievement of learning objectives (5 items), and perceived benefits of the subject in promoting one's personal development (5 items). The second section is related to students' perception of the teaching of the staff member (12 items) which measures teaching quality and attitude of the subject teacher. A 5-point Likert scale was used (1 = strongly disagree and 5 = strongly agree). A high score indicates good quality of the subject.

OUR FINDINGS

Table 1 reports the internal consistency of the SFQ. Cronbach's alpha coefficients for the three subscales regarding the first section of the SFQ (perceived learning experience, achievement of learning objectives, and perceived benefits of the subject in promoting one's personal development) were on the high side (.91, .94, and .94 respectively). The teaching of staff member subscale was also found to be internally consistent (Cronbach's $\alpha = .97$).

To examine the construct validity of the SFQ, confirmatory factor analysis (CFA) was conducted using Amos 22.0. The four scales (namely, perceived learning experience, achievement of learning objectives, perceived benefits of the subject, and perception of teaching staff) were treated as latent factors in the CFA model, and their corresponding items were the observed variables (indicators). Full information maximum likelihood analysis was used to impute for missing data, and the correlations between the latent factors were considered. Figure 1 shows the hypothesized model. The results indicate that the model fitted the data quite well: $\chi^2(df = 293) = 1300.68$, RMSEA = .07 (95% CI from .069 to .077), CFI = .94, TLI = .93. The standardized path coefficients (from the latent factors to the corresponding items) ranged from .79 to .90, and all these paths were significant ($p < .001$). The correlation coefficients among the four latent factors ranged from .71 to .94, $p < .001$ (Figure 2). These findings provide sound evidence for the construct validity of the revised SFQ.

Regarding the responses of the students to the questionnaire, descriptive statistics of students' responses to the SFQ are summarized in Table 1. The mean scores on the three scales of students' perceptions about the subject were all above 3.73, and for students'

perceptions about the teaching staff the mean scale score was 4.14, which suggest that students generally had positive evaluation on the subject and the teacher.

Table 1. Descriptive statistics and internal consistency of the SFQ for TL

Scale	No. of items	Cronbach's α	Mean	SD
Perceived learning experience	4	.91	3.82	.70
Achievement of learning objectives	5	.94	3.82	.71
Perceived benefits of the subject	5	.94	3.73	.72
Teaching of the staff member	12	.97	4.14	.62

Note. LE = perceived learning experience; AO = achievement of learning objectives; PB = perceived benefits of the subject; TS = perceived teaching of the staff member. The rectangles indicate observable variables, and the circles indicate latent variables. The observable variables on the left are the items on the corresponding scales. Standardized path coefficients are reported.

Figure 1. Hypothesized construct model of the student feedback questionnaire for TL.

Note. LE = perceived learning experience; AO = achievement of learning objectives; PB = perceived benefits of the subject; TS = perceived teaching of the staff member. The rectangles indicate observable variables, and the circles indicate latent variables. The observable variables on the left are the items on the corresponding scales. Standardized path coefficients are reported.

Figure 2. CFA results on the student feedback questionnaire for TL.

DISCUSSION

The first purpose of this study was to explore the psychometric properties of the Student Feedback Questionnaire for this course. Royse argued that good psychometric properties of subjective outcome evaluation surveys are necessary for obtaining valid evaluation results [29]. Hence, exploring the reliability and validity of this questionnaire is important for us to know whether student evaluation measured by this questionnaire is objective or not. Results

showed that the Cronbach alpha coefficients for each scale were very high, suggesting that this questionnaire has very good internal consistency reliability. Furthermore, the results of confirmatory factor analysis indicated good construct validity of this questionnaire. Specifically, the absolute and comparative fit indices (RMSEA, CFI, and TLI) suggest that the CFA model fitted the data well. In addition, all the items loaded significantly on their corresponding scales. To summarize, these results indicate that the SFQ for TL used in the current study has good psychometric properties. Methodologically speaking, the findings suggest that the information collected is reliable and valid.

The second purpose of the current study is to investigate the quality and effectiveness of the subject “Tomorrow’s Leaders”. As a large sample of students who took this course in the second semester of 2012/13 academic year completed the SFQ online anonymously, and confidentiality was emphasized during the survey, it is likely that the students might respond to the questionnaire in a genuine way. The high mean score of each scale of the SFQ indicates that students perceived the course as effective and having high teaching quality. Students clearly understood the teaching goals of this course; the subject design was perceived as effective in helping them achieve the learning objectives, and students agreed that this subject has promoted their development of different interpersonal and intrapersonal competences (such as critical thinking, problem solving, moral competence, etc.) which are necessary for leadership and one’s personal growth. These findings support the effectiveness of the subject in its first-year implementation. By enhancing students’ personal development in these important generic skills and leadership qualities, this subject is likely to prepare students to better adapt to the ever changing society, help them become more abled people, and increase their chances to be qualified leaders in today’s world. Moreover, results showed that students evaluated highly on teaching quality of the subject teacher and perceived the workload as appropriate. These results are consistent with students’ evaluations at the initial pilot stage of this subject as an elective subject [13] and suggest that “Tomorrow’s Leaders” was well designed and implemented successfully in its’ first-year implementation.

This study has several practical implications. First, it suggests the effectiveness and necessity of offering leadership and intrapersonal development courses like “Tomorrow’s Leaders” to students in university settings. Character and competence are critical in numerous aspects of one’s life [9]. While programs focusing on moral education and positive youth development are primarily implemented in primary and secondary school periods, the current findings demonstrated a successful example of offering such programs to university students. As reflected in the evaluation finding, students perceived that their overall development was promoted after attending the lecture. The successful experiences of “Tomorrow’s Leaders” could inspire teachers and researchers in other universities to design and implement similar curriculum-based programs for their students. Second, our study provides evidence for the good psychometrical properties of the SFQ for TL. Researchers could be more confident to use this validated instrument to measure the quality and effectiveness of the course in future and make good use of the findings based on the questionnaire to triangulate evaluation results obtained from other methods.

At the same time, this study has several limitations. First, the evaluation of the course in this study was only based on students’ reports. Therefore, these evaluations may not be objective enough. To gain a deeper understanding of the course quality, evaluation of this course based on the views of experienced professionals is needed. Longitudinal studies that examine student changes in leadership qualities and intrapersonal competences before and

after taking this course based on objective measures should be further conducted. Second, as no in-depth information can be generated from e-course evaluation surveys, qualitative studies should be done to supplement the present study which primarily yielded quantitative data. However, it is noteworthy that qualitative studies conducted previously have demonstrated the usefulness of the subject in promoting holistic development in the students [30-32].

ACKNOWLEDGMENT

We thank the Educational Development Centre of The Hong Kong Polytechnic University for the assistance in data collection. The preparation for this paper and the GUR evaluation study are financially supported by the Teaching Development Grant of The Hong Kong Polytechnic University. The authorship is carried equally by the first author and second author. This chapter is based on a paper to be published in the *International Journal of Adolescent Medicine and Health*.

ABSTRACT

Following the North American model, the length of undergraduate programme in Hong Kong has been extended from three to four years since 2012. To maximize the impact of the additional year, The Hong Kong Polytechnic University (PolyU) has implemented a new general education framework entitled “General University Requirements (GUR)” aiming to cultivate students in a holistic manner. This study explored students’ impressions of the GUR subjects using a survey collecting primarily qualitative data. Results from 163 students of eight faculties showed that students perceived the GUR subjects favorably. Having opportunities to make new friends from other departments and the teaching and learning methods, particularly experiential learning stimulated students’ interest and enriched their learning experiences which were reportedly unforgettable. Some of the obstacles encountered by students in several

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

subjects were identified. The beneficial effects of the GUR subjects in different domains were voiced by the students.

INTRODUCTION

Traditionally, universities are solely training grounds for vocational and professional skills. With the impact of globalization and increased competition in society, universities have come with more responsibilities to nurture students with both professional knowledge and “the ‘key’, ‘core’, ‘transferable’ and/or ‘generic’ skills needed in many types of high-level employment” [1]. Similarly, Shafie and Nayan [2] highlighted that employers today are concerned about finding employees who not only possess basic academic skills such as reading, writing, listening, science, mathematics, and oral communication, but also higher order thinking skills (i.e., learning, reasoning, thinking creatively, decision making and problem solving). These skills are believed to be teachable that can be taught in both schools and employment settings [3]. Universities are therefore obliged to equip students with not only professional knowledge but also different desired interpersonal and intrapersonal attributes. On the other hand, increasing emphasis has been placed on student satisfaction which is an optimal indicator of quality [4]. Hence, obtaining student feedback on courses, lecturers, and their university experiences becomes increasingly important in higher education.

Many performance indicators are based on the quantitative data from student feedback surveys. While quantitative surveys are the primary means of obtaining student feedback, Grebennikov and Shah [5] argued that qualitative data received relatively less attention. Likewise, Richardson [6] pointed out that qualitative research on student feedback is extremely sparse. Williams, Coyle, and Healy [7] contended that the drawbacks of quantitative study involve the closed-ended questions which would restrict the respondents to express their negative experiences completely. Additionally, high satisfaction ratings do not necessarily mean that respondents “have had good experiences in relation to the services; rather, expressions of satisfaction may more often reflect attitudes such as ‘they are doing the best they can’, or ‘it’s not really their job to do ...’” [7].

Grebennikov and Shah [5] argued that systematic collection and analyses of qualitative data can be utilized as an effective institutional performance indicator and help improve students’ learning experience. Scott and colleagues [8] stressed that qualitative data are indeed “a lot richer than expected” [5]. For instance, Kabanoff, Richardson, and Brown [9] reported that there were recurring themes regarding different aspects of the course that were not tapped in existing quantitative evaluations of university experience. Studies examining students’ use of online faculty rating sites have found that students considered qualitative comments to be more informative than quantitative rankings [10, 11]. Therefore, the value of qualitative feedback is to “map the scope and strength of issues deemed important by students or graduates” [6]. Scott et al. [8] further suggested that “universities [should] focus more on what students have to say in their own words and incorporate such feedback into their priorities” and “the quantitative and qualitative data should complement each other as together they cover a broader range of student views on their university experience” [8].

Ragin [12] highlighted one of the differences between quantitative and qualitative approaches: “most quantitative data techniques are data condensers. They condense data in

order to see the big picture. Qualitative methods, by contrast, are best understood as data enhancers. When data are enhanced, it is possible to see key aspects of cases more clearly” (p. 93). These two research approaches are commonly used in the field of evaluation. Qualitative evaluation can allow the participants to voice their experiences [13] and enable researchers to gain insights into the processes and outcomes of programs through exploring into participants’ experiences and stories [14]. Royse [15] emphasized that using open-ended questions can allow the researchers to know the problems they never anticipate. More importantly, qualitative study may address some concerns about quantitative surveys that result in inflated satisfaction scores. “Clients often are more critical when qualitative methodologies are utilized, and are free to express their concerns about all aspects of care in a way that is not possible with many surveys. For new and innovative programs seeking to mold their programming around the needs of their clients, it is especially important that their client satisfaction reports be as accurate as possible, not inflated through the use of a poorly crafted survey” [16]. Qualitative evaluation is therefore an appropriate strategy to elicit feedback on newly implemented program.

With a shift from a three-year to a four-year undergraduate education structure since 2012, the curriculum of higher education in Hong Kong had undergone “significant and monumental change” [17]. One of the changes is the inclusion of General Education (GE) in the undergraduate curriculum. Ample literature indicates that numerous universities worldwide have incorporated GE into their undergraduate curriculum as a vital strategy to increase their students’ international competitiveness. In sharp contrast to pure professional and vocational training, GE focuses on the whole development of an individual which includes the development of a wide array of skills, such as language and communication skills, quantitative and analytical skills, planning and investigative skills, critical thinking, and problem solving skills [18] which are highly valued nowadays. Baker [19] argued that higher education should be “much more than a production line for work-ready graduates”. The fundamental job of undergraduate education is to “... help them [students] grow up, to learn who they are, to search for a larger purpose for their lives, and to leave college as better human beings” [20].

The Hong Kong Polytechnic University (PolyU) has developed a new General Education framework entitled “General University Requirements” (GUR) which aims to cultivate five desirable graduate attributes (i.e., critical thinking, effective communication, problem solving, lifelong learning, and ethical leadership). The GUR curriculum includes six major components: Freshman Seminar (FS) (3 credits), Language and Communication Requirements (LCR) (9 credits), Cluster Area Requirements (CAR) (12 credits), Leadership and Intra-personal Development (LIPD) (3 credits), Service Learning (SL) (3 credits), and Healthy Lifestyle (HL) (0 credit). To evaluate the effectiveness of the GUR, a five-year longitudinal project has been conducted since the first introduction of the new four-year undergraduate curriculum in 2012-2013 academic year. While the evaluative findings of the first-year implementation of the GUR were very encouraging [21, 22], it would be helpful if consistent findings can be found for 2013-2014 academic year based on different evaluation strategies. In the present paper, based on the qualitative evaluation sheet, qualitative data were collected to address the following research questions:

1. What were students' overall impressions of the GUR subjects?
2. What were students' most unforgettable experiences while they studied the GUR subjects?
3. What were the difficulties encountered by students while studying the GUR subjects?
4. What were students' perceived benefits of studying the GUR subjects?

OUR STUDY

In late December 2013 (i.e., end of the first semester of 2013-2014 academic year), 320 students were randomly selected from all Year 2 students enrolling in the four-year curriculum of PolyU in the 2012-2013 academic year. Forty students were randomly selected from each faculty/school. Emails and phone calls were sent to students to invite them to participate in the GUR qualitative evaluation. Students were asked to fill in a qualitative evaluation sheet attached to the invitation email. Before the commencement of the second semester of 2013-2014 academic year, 163 students returned the completed evaluation sheet (response rate = 50.94%). The number of participants who completed the qualitative evaluation sheets in each faculty was: Faculty of Applied Science and Textiles (FAST) (n = 18), Faculty of Business (FB) (n = 20), Faculty of Construction and Environment (FCE) (n = 21), Faculty of Engineering (FENG) (n = 20), Faculty of Humanities (FH) (n = 20), Faculty of Health and Social Sciences (FHSS) (n = 22), School of Design (SD) (n = 22), and School of Hotel and Tourism Management (SHTM) (n = 20).

A qualitative evaluation sheet developed by the research team was used to examine students' views on the GUR subjects that they enrolled in semester one of 2013-2014 academic year. The qualitative evaluation sheet consists of the following parts:

- Three descriptors/short phrases that were used by students to describe their general impressions and feelings towards the GUR subjects;
- Students' unforgettable experiences in studying the GUR subjects;
- Difficulties/challenges encountered by students in studying the GUR subjects;
- Students' perceptions of the benefits of the GUR subjects to themselves.

All the responses in the qualitative evaluative sheets were entered in the computer for analyses. The unit of analysis was a meaningful unit instead of a statement [23]. For instance, a comment on one's general impression about GUR subjects, "interesting and relaxing" would be broken down into two meaningful units, i.e., "interesting" and "relaxing". Meanwhile, descriptions with the same meaning would be grouped into the same attribute category. After initial coding, all units were further categorized into four categories: "positive", "negative", "neutral", and "undecided". To enhance the reliability of the coding, both inter-rater and intra-rater reliabilities were examined. For the inter-rater reliability, a research assistant with a Master degree who did not know the original coding recoded 20 randomly selected responses from students after the completion of the raw coding. The inter-rater agreement for these responses was 90%. For the intra-rater reliability, a post-doctoral fellow who coded the raw data recoded the above 20 randomly selected students' responses. The intra-rater agreement percentage for the responses was 90%.

FINDINGS

Since the majority of students had completed the FS and LIPD in the first year, the findings reported focused primarily on students' perspectives on subjects of LCR-English and LCR-Chinese, CAR, SL, and HL which they enrolled in 2013-2014 academic year. First, most students used positive descriptors to describe their general impressions and feelings towards the GUR subjects. The categorizations of descriptors are shown in Tables 1-5. The total number of descriptors for each GUR component was: LCR-English ($n = 96$), LCR-Chinese ($n = 58$), CAR ($n = 232$), SL ($n = 70$), and HL ($n = 185$). Among the descriptors for each GUR component, the number and percentage of positive responses were: LCR-English ($n = 70$, 72.92%), LCR-Chinese ($n = 35$, 60.34%), CAR ($n = 129$, 55.60%), SL ($n = 49$, 70.00%), and HL ($n = 144$, 77.84%). Some common positive descriptors across the GUR subjects included "interesting", "practical", "useful", "helpful to development" and "have increased knowledge" whereas the negative responses were "heavy workload" and "boring".

Table 1. Categorization of the descriptors about the LCR-English subjects

Descriptors	Nature of the descriptor				Total
	Positive	Neutral	Negative	Undecided	
Improvement in English	5				5
Improvement in English reading	2				2
Improvement in English writing	3				3
Interesting	9				9
Helpful to my development	5				5
Interactive	2				2
Useful	9				9
Ok	3				3
Inspiring	4				4
Practical	6				6
Appropriate amount of assignment	2				2
Very useful	2				2
Helpful	4				4
Other positive descriptors (e.g., enjoyable, communication skill improvement)	14				14
Want to know more grading criteria		1			1
Could shorten class time		1			1
Hope to teach reflection- or report-writing instead of essay-writing		1			1
Heavy workload			3		3
Difficult			2		2
Other negative descriptors (e.g., boring, troublesome)			13		13
Challenging				2	2
American style is better than British style				1	1
Academic-oriented				1	1
Easy to get a bad grade				1	1
Total count	70	3	18	5	96
(Percentage)	(72.92%)	(3.13%)	(18.75%)	(5.21%)	(100%)

Regarding students' unforgettable experiences in studying the GUR subjects in semester one of 2013-2014 academic year, 84 meaningful responses were extracted from the raw data which were further categorized into 30 categories. Among these meaningful responses, 64 (76.19%) were regarded as positive responses, 7 responses (8.33%) were categorized as

neutral and 13 responses (15.48%) were counted as negative responses (see Table 6). Specifically, responses pertaining to students' unforgettable experiences were related to two domains: teaching and learning as well as perceived benefits of the GUR subjects. Regarding the realm of teaching and learning, experiential learning experience in Service Learning subjects, having been taught by a good teacher, and studying subjects not related to the major discipline were reported by the greatest number of students as unforgettable. In addition, having opportunities to learn different kinds of interesting sports and making new friends from other faculties were often cited as unforgettable experiences by students. Nevertheless, some negative experiences were also reported, including the difficulty to enroll in one's desired GUR subjects, long lecture time and heavy workload in some subjects, and having free-rider in group work.

Table 2. Categorization of the descriptors about the LCR-Chinese subjects

Descriptors	Nature of the descriptor				Total
	Positive	Neutral	Negative	Undecided	
Improvement in Chinese writing	4				4
Improvement in Putonghua	3				3
Interesting	6				6
Relaxing	2				2
Helpful to my development	5				5
Useful	2				2
Improvement in communication skill	2				2
Other positive descriptors(e.g., knowledge broadening, inspiring)	11				11
Content not very difficult		1			1
Can be more interesting		1			1
Neutral		1			1
Boring			2		2
Not very useful			2		2
Too many tests			2		2
Other negative descriptors (e.g., Heavy workload, Dreary)			9		9
Not many assignments				1	1
Challenging				1	1
Easy to get a bad grade				1	1
Should not teach Putonghua				1	1

No use			2		2
Troublesome			2		2
Long service hour			2		2
Other negative descriptors(e.g., messy, unclear marking scheme)			8		8
Challenging				1	1
Need time to prepare				1	1
Need self-initiative				1	1
Many different kinds of work in different SL subjects				1	1
Total count	49	0	17	4	70
(Percentage)	(70.00%)	(0.00%)	(24.29%)	(5.71%)	(100%)

For obstacles or challenges encountered by the students, 101 meaningful responses were extracted from the raw data (see table 7). These responses were further categorized into 24 types of difficulties or challenges within eight broad categories: language, time management, group work, assignment and assessment, teaching and learning, lengthy and timetable of class, subject registration and fulfillment of requirements. The challenges that gained relatively higher frequency of responses included: CAR subjects enrolled with little knowledge of the background (16.83%), heavy workload (11.88%), and time management (10.89%). More specifically, the contents of some CAR subjects were perceived by students to be abstract and difficult. Students expressed that they had heavy academic workloads, and poor time management was another challenge to students.

Table 5. Categorization of the descriptors about the HL subjects

Descriptors	Nature of the descriptors				Total
	Positive	Neutral	Negative	Undecided	
Interesting	29				29
Relaxing	14				14

A total of 163 meaningful responses related to the students' perceived benefits derived from GUR study were extracted from the raw data. Among the 163 meaningful responses, 156 (95.71%) were regarded as positive responses which were further categorized into "five desired graduate attributes", "other competences", "character", "health", "learning and knowledge", and "others" domains (see Table 8). Among the five desired graduate attributes, many students reported that they have improved their communication skills, developed their

critical thinking skills, and ethical leadership skills. Additionally, students expressed that their knowledge has been broadened.

These benefits can be seen in the narratives below excerpted from students' responses:

"Most GUR subjects required us to work with other classmates on some projects and presentations. It helped my personal development through enhancing my communication skills and teaching me how to cooperate with others and accomplish some goals with them."

Table 7. Categorization of students' difficulties/challenges in GUR study

Difficulties / Challenges	N	%
Language		
Difficulty in catching up with language courses due to inadequate language foundation	3	2.97
Difficulty in catching up with courses taught in English due to inadequate language foundation	5	4.95
Difficulty in practicing English and Chinese in LCR subjects	1	0.99

DISCUSSION

Due to a paucity of research findings on the effectiveness of GE in Hong Kong, this study attempted to fill the knowledge gap and to evaluate the effectiveness of the GUR program at PolyU in the 2013-2014 academic year based on a qualitative evaluation of students. The present study is an important contribution to the field as systematic qualitative evaluation studies involving a large sample is lacking in the field. There are several unique features of the study. First, this is the first known qualitative study examining the 4-year curriculum in Hong Kong. Second, a large sample of students from different faculties was recruited. Third, both quantitative and qualitative analyses were carried out. Finally, inter and intra-rater reliability checks were conducted for analyses.

Concerning the students' impressions of the GUR program, the results showed that students generally had positive perceptions of different GUR subjects, with the positive responses ranging from 55.60% to 77.84% across components. The majority of students perceived the contents of GUR subjects as interesting and conducive to learning additional knowledge and skills beyond their majors. The active and engaging teaching and learning (T&L) methods used in different GUR components helped enhance students' learning experiences that augment the learning outcomes. There were also less favorable views expressed by students such as heavy workload and relatively boring content, which suggest the need to further examine the syllabus and teaching in some GUR subjects.

Regarding unforgettable experiences in studying the GUR subjects, approximately 76.19% were positive responses, suggesting that students had remarkable, positive learning experiences. As mentioned above, students expressed appreciation of the T&L methods, in particular the experiential learning and collaborative learning (e.g., group project) adopted in many GUR subjects. Numerous studies have found that experiential learning can develop students' competences, link their learning to practice, and provide students with profound learning experiences [24, 25]. Group work helps promote work-related skills, develop deeper understanding of complex tasks, and manage time-consuming tasks [26]. The UK Quality Assurance Agency for Higher Education guidelines for economics considers group work as vital because it provides "active and deep learning opportunities for students' learning" [27, p1]. Experiential learning, group work, and other student-centered T&L methods actively engage students, improve the T&L experience, and offer fruitful and satisfying learning experiences to students so they found their learning unforgettable. In addition, having been taught by good and enthusiastic teachers made students' learning experiences unforgettable.

On the other hand, some undesirable experiences were also noted. First, one of the negative experiences was the difficulty to enroll in students' interested CAR subjects through the current subject registration system. In fact, this issue has been reported in the first year of GUR implementation [22] and administrative strategies have been conducted to address the problem, such as adjusting the timetable of CAR subjects so that students would have more flexibility in subject selection. The current finding seems to suggest that more strategies shall be attempted to further resolve this problem. Another negative experience reported by students was the free-riding problem in group work. According to Morris and Hayes [28], the free-riding problem refers to "the problem of the non-performing group member who reaps the benefits of the accomplishments of the remaining group members with little or no cost to him/herself" [28]. Free-riding behavior of a student can demotivate diligent students in the

same group. Therefore, teachers should provide close monitoring to students and are encouraged to adopt strategies such as identifying individual contribution by group members in the process of evaluating the project work [29]. This method has been used in one of the GUR LIPD subjects, “Tomorrow’s Leaders”, which effectively reduces the free-riding problem in group work.

Several obstacles or challenges students encountered in their GUR study are noted. First, the contents of CAR subjects were perceived too advanced for some students. These results were congruent with those of Shek et al. [22] who found that students from humanities and social sciences backgrounds expressed difficulty in studying science-based CAR subjects as these students had little or no background knowledge. Morgan and Tam [30] found that difficult content was one of the barriers often cited by non-persisting university students who subsequently dropped out from the course. The implication is that GUR teachers shall reflect on the level of difficulty of the subjects they offered and make adjustment on the lecture content to cater to the needs of students at different knowledge levels.

Second, students reported that the workload of some GUR subjects was heavy. Gardner and Parkinson [31] found that university students who reported having heavy subjective workloads were more stressed. Kember [32] noted that excessive perceived workload encourages surface approaches to learning because students tend to resort to undesirable study approaches to deal with the work demand. Teachers should help identify those students in need of additional assistance for their homework and simultaneously, set appropriate workload which was found to be significantly related to a deep approach to learning in students [33]. The promotion of effective communication between students and teachers is also recommended as it can help teachers set some reasonable expectations from students. Another problem was poor time management which, coupled with perceived excessive homework and poor time management skills, can be an important source of stress for students.

Lastly, an obstacle reported by students was the difficulty in writing long English paper or report for the GUR subjects and the guidance from teachers to complete the assignment was not clear. Similar results were reported by Lee and Tajino [34] who found that the first-year Japanese university students perceived difficulty in writing English. They explained that a possible reason for expressing a higher perception of difficulty in writing English paper or report was students’ perception of their low English ability. A local Education Commission report in Hong Kong on language proficiency in the mid-1990s has already noted that “... many of our upper secondary schools do not have the English proficiency required by tertiary education institutions or the vocational sector” [35]. To address this need, the Office of General University Requirement (OGUR) has organized a series of workshops for students to learn how to write reflective papers and prepare group presentation starting from 2013-2014 academic year. Students participated in the workshops expressed satisfaction and gained more self-efficacy in handling such assignments. Other methods, such as peer-partner learning may be further attempted.

Students perceived that the GUR subjects had beneficial effects on their development, with 95.93% of the responses coded as positive. Students considered the GUR subjects were able to increase their knowledge, different competence, character, and health (i.e., both physical and mental health). Evidently, the GUR components were perceived as conducive to the development of generic attributes in students, especially of the five desired graduate

attributes of PolyU as revealed in the narratives of the students. These findings are generally consistent with the findings based on the first year findings of the GUR longitudinal study.

Nevertheless, several limitations of the study should be noted. First, although the qualitative evaluation is the optimal strategy to collect different participants' perspectives, its conclusion is limited when making generalization or representativeness to a larger population [36]. Second, this study only focused on the students' perspectives on the GUR subjects, while the views of other stakeholders such as teachers should also be examined in order to obtain a more comprehensive picture. In addition, other evaluative methods such as objective outcome evaluation and longitudinal case study on students should be adopted to triangulate the findings from the current study. Despite these limitations, the present study provides valuable qualitative evaluation findings which support the effectiveness of the GUR in developing the desired graduate attributes among university students in Hong Kong.

ACKNOWLEDGMENTS

The GUR evaluation study and the preparation of this manuscript are financially supported by the Teaching Development Grant, The Hong Kong Polytechnic University. This chapter is based on a paper to be published in the *International Journal of Adolescent Medicine and Health*.

ABSTRACT

This chapter evaluated a university general education subject on leadership and intrapersonal development ("Tomorrow's Leaders") offered at The Hong Kong Polytechnic University based on an online survey using the Student Feedback Questionnaire (SFQ). At the end of the first semester of 2013/14 academic year, 725 year-one students completed the online questionnaire. Results showed that the students generally had positive ratings on both the subject attributes and the qualities of teachers. The majority of the participants perceived the subject as beneficial to their holistic development and leadership competencies. Students from Faculty of Health and Social Sciences and Faculty of Applied Science and Textiles had more favorable evaluation of the subject than did students in Faculty of Construction and Environment. Students'

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

perceived benefit of the subject was significantly predicted by the subject attributes and teacher attributes. Implications of the findings are discussed.

INTRODUCTION

There is a growing concern about the mental health of university students nowadays and their competencies to successfully integrate into future workforce after graduation. In particular, as a Special Administrative Region (SAR) of China and a major financial and service center, the changing economy of Hong Kong has placed high demands and challenges to university students. Empirical studies have revealed high rates of emotional and anxiety problems in first-year university students in Hong Kong [1]. According to the results of a recent survey, more than 80% of the local business leaders considered today's university graduates as having insufficient personal and interpersonal abilities to adapt to the rapidly changing market [2]. To better prepare students to meet the demands and challenges, the Education Commission of Hong Kong Government had launched a university education reform starting from 2012/13 academic year which extended the traditional three-year undergraduate programme to four years [3]. With the one extra year, universities are expected to provide a series of General Education subjects for students to promote their personal growth and holistic development.

As one of the eight public universities in Hong Kong, The Hong Kong Polytechnic University (PolyU) has designed and implemented a general education framework (the General University Requirement, GUR) for all students enrolled in the new four-year undergraduate curriculum [4]. Under the GUR framework, one important area is the "Leadership and Intra-personal Development" (LIPD), which aims to promote students' holistic development and leadership qualities based on experiential learning. The LIPD component of the GUR consists of two subjects: "Tango! Managing Self and Leading Others" (Tango) and "Tomorrow's Leaders" (TL). While Tango was designed by the Faculty of Business and offered to their own students, TL is offered to all first-year undergraduate students as a compulsory course since the launch of the new 4-year undergraduate programme in 2012/13 [1].

Specifically, TL has adopted multiple teaching and learning approaches, such as lectures, group discussion and debates, reflective writing, and role play, to achieve the intended learning outcomes of the LIPD component. As the subject is offered in a large scale (more than 2,000 students enrolled every year), it is important to understand how well the subject has been implemented and to what extent it has promoted students' personal development. Since 2012/13, systematic evaluation studies have been conducted to examine the implementation and effectiveness of TL, including pre- and post-test survey based on objective outcome indicators, focus group interviews with students and teachers, post-lecture evaluation, post-course evaluation, and students' reflective journals [6-9]. The findings converged to suggest an overall success of the subject in promoting students' holistic development. For example, findings on students' reflective journals ($n = 62$) in 2012/13 revealed that students perceived the subject as beneficial in improving their self-understanding, self-management, communication skills, and ethical leadership. Adopting a one group pretest-posttest design, Shek and Ma reported that students showed positive changes in self-determination, thriving, and life satisfaction after completing the subject

based on objective outcome measures in 2012/13 [7]. Based on student feedback questionnaire, it was found that students had positive perceptions about the subject content, quality of the teaching staffs, and overall effectiveness of the subject [9].

Although TL can be regarded as successful in its first-year implementation, the teaching environment and conditions are always changing. In fact, several factors changed in the second year which might influence the implementation of the subject. First, to meet the needs of the large number of students, new academic staff was recruited to teach this subject. Second, the average class size in 2013/14 was larger than that in 2012/13 which resulted in some changes in teaching strategies. For example, in classes with more than 90 students, some of the originally designed interactive activities cannot be implemented thoroughly. Third, the curriculum was refined based on the post-lecture feedback collected from students in 2012/13. Under these new conditions, it is necessary to know whether the subject remained to be effective and well-received by students.

An interesting observation based on previous findings is that students from Faculty of Engineering (FENG) and Faculty of Applied Science and Textiles (FAST) had more positive views about the subject than students of other disciplines [9]. This is inconsistent with the general findings that students majoring in social sciences or “soft” disciplines (e.g., arts and humanities) often reported more favorable attitudes toward general education subjects than did students majoring in sciences [10, 11]. It was speculated that both the good quality of teaching demonstrated by teachers who delivered the subject to students of these two faculties and the unique characteristics of the subject contributed to students’ positive evaluation result. In 2013/14, as all teaching staff were randomly assigned to teach different classes, it would be interesting to further examine whether the evaluation by students from different faculties would still be different following the same pattern revealed in the previous academic year.

Moreover, while empirical studies have suggested program attributes (e.g., plan, design and delivery approaches) and program implementer characteristics (e.g., personal experience and attitudes) were crucial factors to the success of a program [12-14], there is little research focusing on curriculum-based program in university settings, particularly in Hong Kong. Based on student feedback collected in 2012/13 about TL, Shek and Yu [9] reported that only students perceived qualities of teaching staff (but not subject attributes) significantly predicted students’ final grade in the subject. One limitation of the study was that students’ final grade might not fully reflect their learning outcomes as some personal development such as self-reflective skills or interpersonal competences may not be immediately shown in one’s term paper or presentation. As such, it would be informative to investigate the factors that contribute to students’ perceived benefits of the subject.

Against the above background, the current study was intended to address the following three research questions: [1] how did students evaluate the subject “Tomorrow’s Leaders” (TL) in 2013/14 based on the validated Student Feedback Questionnaire (SFQ)? [2] Would students’ SFQ ratings on TL vary across faculties? [3] How would students’ perceived subject attributes and teacher qualities predict students’ perceived benefits of TL?

OUR STUDY

In total, 1,070 year-one students from 17 classes took TL in the first semester of 2013/14 academic year. Near the end of the semester, all students were invited to participate in the online SFQ survey through an email sent by the Educational Developmental Centre (EDC) of the University. Purpose of the survey, confidentiality of participation, and the link to the online questionnaire were highlighted in the email. Clear instructions on how to answer the questions were provided at the beginning part of the questionnaire. After students completed and submitted the questionnaire, their data were saved in the database of Information and Technology Services Office (ITS) in an automatic way. To assure the confidentiality, the database was only accessed by research staff in EDC who provided the data for the present study.

Seven hundred and twenty-five students agreed to participate and completed the questionnaire, indicating a good response rate of 67.8%. Among the 725 students, there were 72 students from Faculty of Humanities (FH); 47 from Faculty of Construction and Environment (FCE); 261 from Faculty of Engineering (FENG); 97 from School of Hotel and Tourism Management (SHTM); 100 from Faculty of Health and Social Sciences (FHSS), and 148 from Faculty of Applied Science and Textiles (FAST). Students from Faculty of Business (FB) and School of Design (SD) did not evaluate the subject, as FB students took another LIPD subject (Tango) and SD students would take the subject in the second semester of 2013/14. The survey was administered anonymously online without asking students to report any identifiable individual information. Therefore, the characteristics of the participants were unknown.

The Student Feedback Questionnaire (SFQ) developed by EDC was used in this study [15-16] which examines students' evaluations about the subject on two dimensions: the "subject attributes" (learning experience and achievement of learning objectives) and the "teacher attributes" (qualities of teachers) [16]. To evaluate TL, two subscales with extra questions were added: perceived benefits of the subject (5 items) and other qualities of the teaching staff (5 items). The modified version of SFQ for TL thus constitutes three dimensions: "subject attributes", "teacher attributes (including both the original items and the newly added items on other qualities of the teaching staff)", and "perceived benefits of the subject" (5 items). Cronbach's alphas of the modified SFQ and its subscales ranged from .92 to .98, which indicated sound reliability of the questionnaire based on the present sample. All items of the scale were scored on a 5-point Likert scale (5 = *strongly agree*, 4 = *agree*, 3 = *no strong view*, 2 = *disagree*, 1 = *strongly disagree*). Scale score and subscale scores were calculated by averaging the related item scores, with higher score representing for a more positive evaluation.

First, to examine students' general evaluation about the subject, descriptive statistical analyses were conducted including numbers and percentages of students with different responses on each item. Means and standard deviations of different subscale scores and the SFQ scale score were also calculated. Second, to investigate whether students from different faculties had different perceptions toward the subject, MANOVA was conducted to compare students' SFQ ratings across faculties. Faculties were considered as the independent variables and students' SFQ scores on subject and teacher attributes as well as perceived subject benefits were regarded as the dependent variables. One-way ANOVA was also carried out to

examine faculty differences in students' overall SFQ score, with faculty being treated as the independent variable and students' overall SFQ score as the dependent variable. Third, to investigate the predictive effects of students' evaluation on subject attributes and teacher attributes on their perceived benefits of the subject, multiple regression analyses were performed. Students' SFQ scores on subject attributes and teacher attributes were treated as the independent variables and perceived benefits of the subject was considered as the dependent variable. All the analyses were performed using the statistical package of SPSS 20.0.

FINDINGS

Descriptive results were presented in Table 1 and Table 2. Several observations can be highlighted from the findings. First, in terms of subject attributes, the majority of students had favorable learning experiences and perceived that the subject has helped them achieved the learning objectives. For example, 77.6% of the participants agreed that the assessments require them to demonstrate their knowledge, skills and understanding of the subject, and most of the participants believed that the subject has enabled them to develop a good understanding of the qualities of effective leaders (77.0%) as well as a better self-understanding (75.0%). Second, students gave high ratings on the qualities of the teaching staff. More than 90% of the students considered the subject teachers as well prepared for the lessons and being willing to provide help when necessary. A large proportion of students believed that the staff member had good teaching skills (83.5%) and professional attitudes (88.7%). Students also appreciated teachers' interactions with students (87.0%), logical and clear subject content organization (86.1%), and timely class feedback (84.2%). Overall, the majority of the students (84.7%) indicated that the teaching staff was an effective teacher, who provided them with a valuable learning experience (82.4%). Third, students generally perceived the subject as beneficial to their holistic development, including understanding of ethical leadership (74.2%), critical thinking (65.4%), communication skills (71.0%), problem-solving skills (59.8%), and personal growth (75.7%). Fourth, the mean scores of SFQ scale and subscales were all above 3.79 out of a maximum of 5 (Table 2). All these findings suggest that students were satisfied with the subject and the teaching staff. They also perceived the subject as having a positive influence on their personal development.

Means and standard deviations of SFQ subscale and scale scores rated by students from different faculties were summarized in Table 3. Results of MANOVA showed that SFQ subscale scores differed significantly across faculties, Wilk's $\Lambda = .95$, $F(10, 1288) = 3.25$, $\eta^2 = .03$, $p < .001$. Post-hoc comparisons using Bonferroni procedure revealed that students of FENG, FHSS, and FAST rated subject attributes significantly higher than did students of FCE ($ps < 0.05$); students from FHSS and FAST also gave higher ratings on teacher attributes than did students from FH and FCE ($ps < 0.001$). Regarding perceived benefits of the subject, FHSS and FAST students showed more positive ratings than did students of FCE. SFQ ratings among other faculties were not significantly different. Similar results were obtained when comparing the overall SFQ scale score across faculties based on ANOVA, $F(5, 645) = 3.46$, $\eta^2 = .03$, $p < .001$. The total scale scores of SFQ given by students of FHSS and FAST were significantly higher than the scores given by students of FCE. Overall, the comparison

findings indicated that students in FHSS and FAST had more positive perceptions about the subject while students in FCE showed less favorable evaluation.

The inter-correlations among different subscale scores and scale score of SFQ were reported in Table 5. All SFQ subscale scores were positively correlated with each other. Results of multiple regression analyses (Table 6) showed that both subject attributes ($\beta = .47$, $p < .001$) and teacher attributes ($\beta = .46$, $p < .001$) significantly predicted students' perceived benefits of the subject. The two predictors together explained 84% of the variance of the dependent variable.

DISCUSSION

This study evaluated the subject "Tomorrow's leaders" based on student feedback in its second-year implementation at The Hong Kong Polytechnic University. Results showed that students generally held positive perceptions on the subject in terms of subject attributes, teacher attributes and perceived subject benefits. The majority of students rated their learning experiences and the achievement of learning outcomes in the subject positively. The qualities of teaching staff were considered high. Students also believed that the subject effectively promoted their personal development in different interpersonal and intrapersonal domains. These findings are generally consistent with the results based on other evaluative studies as well as findings obtained in the first-year implementation of the subject [6-9]. In conjunction with previous reports, the present study provides further evidence for the effectiveness of the subject and suggests that the subject remained well-received by students in 2013/14 academic year.

Students from Faculty of Health and Social Sciences (FHSS) and Faculty of Applied Science and Textiles (FAST) expressed more favorable evaluation than did students from Faculty of Construction and Environment (FCE) in almost every dimensions of SFQ. The pattern is similar to the findings reported by Shek and Yu [9] based on data collected in 2012/13 academic year. While FAST students remained to have more favorable attitudes towards TL, FCE students continuously showed less positive perceptions about the subject. As mentioned, the teaching staff was randomly assigned to students of different faculties in each year, and therefore, it is unlikely that the faculty-based difference in SFQ ratings was due to the qualities of teaching by different staff members. Researchers have suggested that students' motivation in studying a subject would contribute to their ratings of the subject [17]. It is possible that FAST and FHSS students had higher motivation than did students of FCE in studying TL, which led to their different ratings on the subject. This speculation needs to be further investigated by examining students' learning motivation in this subject and controlling this factor when comparing SFQ ratings across faculties. Other possible factors may include the preferred learning styles of students in different majors and their respective academic goals in relation to the subject. Such student characteristics and their influences on SFQ ratings could be interesting topics of future research. Meanwhile, given the relatively low ratings of FCE students, teachers and subject designers of TL need to consider how to further improve the motivation of these students and adjust the teaching mode to better cater the needs and learning styles of FCE students.

Subject attributes	.49	.05	.47***	
Teacher attributes	.56	.05	.46***	.84***

Note: ^aSubject attributes = mean score of I1-I9; ^bteacher attributes = mean score of II1-II12; ^cperceived benefits of the subject = mean score of I10-I14.

*** $p < .001$.

Both subject attributes and teacher attributes significantly predicted students' perceived benefits of the subject. This finding concurred with the results of previous studies that V showed students' learning outcomes were largely influenced by the qualities of the subject and students' perceptions about the instructor [14, 18-20]. In other words, both the subject itself and the person who delivered the subject play an important role in helping students to achieve the intended learning objectives. It should be noted that compared to teacher attributes, the effect of subject attributes was relatively higher, which is different from the findings reported by Shek and Yu [9] that when students' final grade was used as the indicator of students' learning outcomes, only teacher attributes showed significant predictive effects. This may be due to the fact that students' score in the subject can only partially reflect students' learning outcomes. As a subject focusing on students' interpersonal and intrapersonal development, both short-term and long-term effect shall be considered when evaluating the effectiveness of TL. If students perceive the subject as effective, they would be more willing and likely to apply the knowledge and skills acquired in the subject in their future life, i.e., long-term effects. Therefore, when evaluating students' learning outcomes, both objective indicators (such as students' final grade) and subjective indicators (e.g., perceived benefits of the subject) must be taken into account. Overall, the current findings

indicate that both the good design of TL and highly qualified teachers promoted students' effective learning in this subject [21].

The present study has several limitations. First, when evaluating the implementation and effectiveness of the subject, although students' perceptions are important, views of other stakeholders cannot be overlooked. To comprehensively understand the effectiveness and implementation of the subject, future studies may collect views from the subject teachers and other staff from different faculties who may witness the changes of their students (such as the academic advisors). Second, the present study based on quantitative design was unable to provide a detailed narrative of participants' perceptions toward the subject and the reasons behind [22]. Qualitative evaluation is necessary for the researchers to further understand the current findings, such as the reasons why FCE students held relative less favorable attitudes than did students of FAST and FHSS. Third, due to anonymity of the data, no student individual characteristics were included in the analyses. It would be interesting to look at how these factors may affect students' learning experience and outcomes in this subject in the future.

Despite these limitations, the study affirmed the overall smooth and effective implementation of the general education subject, "Tomorrow's Leaders", in 2013/14 academic year based on student feedback. Both subject attributes and teacher attributes significantly predicted students' perceived benefits of the subject. Given the limited evaluative research on curriculum-based interpersonal and intrapersonal programs in university settings, the present study is an important addition to the literature.

ACKNOWLEDGMENTS

This work and the project entitled "The longitudinal evaluation of the General University Requirements under the new 4-year curriculum" are financially supported by the Learning and Teaching Committee at The Hong Kong Polytechnic University under Learning and Teaching Development Funding. The authorship is equally carried by the first author and second author. This chapter is based on a paper to be published in the *International Journal of Adolescent Medicine and Health*.

Chapter 192

HISTORY AND BACKGROUND OF VASCULITIS

Eric L. Matteson*, MD, MPH

Division of Rheumatology, Department of Medicine,
Division of Epidemiology, Department of Health Sciences Research,
Mayo Clinic College of Medicine, Rochester, Minnesota, USA

ABSTRACT

The descriptions of previous poorly understood and obscure diseases by early workers, and their insights and discoveries that followed have formed many of the foundations of modern medicine. The original descriptions of inflammatory vascular diseases in particular shaped the cultural context of medical science and provided the catalysts and inspirations that fueled later clinical investigation. The transition from the so-called *romantic era* to the *scientific era* of medicine in turn mirrored advances in the pathogenesis, treatment and classification of the vasculitides. The stories of the early contributions from Hippocrates to Kussmaul will forever guide clinicians in the fundamental humanity of this discipline.

Keywords: vasculitis, history

INTRODUCTION

The study of the history of vasculitis provides insights into the evolution of clinical thinking and the pathophysiologic that guided the evolution of concepts integral to the modern appreciation of this fascinating group of diseases. Forms of idiopathic vasculitis were identified as early as the nineteenth century, moreover accounts of idiopathic vasculitis in the form of what is presently termed Behçet disease can be found in the writings of Hippocrates [1] as can those related to giant cell arteritis by the oculist Ali ibn Isa in Baghdad in 1000 AD [2].

VASCULITIS IN HISTORICAL CONTEXT

The introduction of scientific methodology in the nineteenth replaced brought to a close the romantic era of medicine and ushered in the scientific era, promoted by the advent of university-based systematized anatomic pathology and technical developments notably microscopic anatomy. Such advances were critical to the development of theories of the cellular basis of disease embraced by Rudolf Virchow and others between 1848 and 1858 [3, 4].

Yet even in 1554, Antoine Saporta [5] provided the classical description of non-traumatic macrovascular disease related to infectious disease due in the occurrence of syphilitic aneurysms in an affected patient. Over time, anatomic pathologists frequently noted inflamed vessels. By the early nineteenth century, infection was accepted as a cause of vasculitis [6, 7] and other forms of vascular disease were more clearly delineated including atherosclerotic disease and developmental arterial disease of the arteries [8]. The first clear description of non-infectious vascular inflammation was likely by Joseph Hodgson in 1815 [9] in his inspection of large arteries at postmortem examination and the recognition of arterial intimal inflammation suggesting that such changes could result from high intravascular pressure, trauma, and a systemic inflammatory state. Moreover, vascular inflammation previously related only to syphilitic infection, could also be associated with other diseases [9]. During the same era, John Hunter [10] described inflammation of the veins.

The advent of microscopy enabled further investigation of the nature of vascular inflammation and its origins. The anatomic pathologist Karl von Rokitansky, who viewed arteritis as having its origin in the adventitia, was unlike Virchow who employed careful microscopic studies of his anatomic specimens and postulated that inflammation instead began in the intima and media [3, 11].

Polyarteritis Nodosa

Adolf Kussmaul and Rudolf Maier described the first clearly recognizable patient with idiopathic vasculitis of the polyarteritis nodosa type (PAN) in 1865 [12] in a 27-year-old journeyman, the findings of whom influenced and systematized later observations. The patient, Carl Seufarth had improved from a prior infectious illness one month earlier when he was arrested in destitute circumstances after wandering into the city of Freiburg, in the Black Forest of Germany during the summer of 1865, and taken to the municipal jail where the officers recognized his poor medical state. He was later transferred to the University of Freiburg Internal Medicine Clinic where he was and was able to walk up the two flights of stairs to Dr. Kussmaul's office, where he examined him, and thereafter hospitalized. Over the ensuing months, Seufarth developed fever, generalized muscle aching, mononeuritis multiplex of the arms and legs, abdominal pain, and proteinuria. He died on May 30, 1865 and an English account of his case was later published [13]. Working closely together with Kussmaul, the anatomic pathologist Rudolf Maier, at the University of Freiburg performed detailed postmortem microscopic examination and described the findings under the rubric of periarteritis nodosa, and later PAN. In their words, there was a "peculiar, mostly nodular thickening of countless arteries of and below the caliber of the liver artery and the major

branches of the coronary arteries of the heart, principally in the bowel, stomach, kidneys, spleen, heart, and voluntary muscles and, to a lesser extent, also in the liver, subcutaneous cell tissue, and in the bronchial and phrenic arteries” [12]. The nodular thickened vessels revealed inflammatory changes in the media and adventitia. The kidneys had changes of “acute Bright’s disease.” Maier wrote, *“The change affects the intralobular arteries, which have glomeruli at their bifurcations, and extends into these branches and even into the glomeruli”* [12].

Kussmaul and Maier ascribed the pathological alterations in the arteries to “inflammation of the arteries affecting principally the perivascular sheath, in which the media also had a part, at least in its outer layers,” recognizing that the inflammatory changes “often attacked neighboring tissues in the opposite direction, for example, the renal parenchyma, connective and muscle tissues.” The investigators initially considered the disease to be a result of infectious causes including a worm infestation, both because of the peculiar nature of the pea-size nodules, which appeared in the tissue below the epidermis of Seufarth’s abdomen, and the thickened fibrotic nature of the affected vessels. Indeed, an abstract cited their patient as an example of nematode aneurysmal disease before Maier [14] conducted a later thorough microscopic evaluation.

There may even have been earlier cases of PAN, but none was so recognized in the medical literature. Karl von Rokitansky provided a very brief clinical description of a patient seen in 1852 at the University of Vienna found to have fatal aneurysmal coronary and mesenteric arterial changes [15] believed to be an early example of PAN. However, Rokitansky did not undertake microscopic examination of the tissue, and it was not until his student Hans Eppinger later examined the specimens microscopically that it was clear that the patient had PAN [16]. Kussmaul did not consult Rokitansky about his earlier patient because of his unfavorable experience as a visiting clinician in Rokitansky’s Institute of Anatomic Pathology institute at about 1840. Instead, he collaborated with Virchow who affirmed that while he might have seen a similar patient but did not understand its fundamental nature [12, 17]. Attesting to the rarity of the disorder, only about 30 additional cases were described in Europe and the United States in the ensuing four decades [17-19], and into the twentieth century.

Necrotizing Vasculitis

The first cases of vasculitis were macroscopically apparent and could be assessed with the naked eye. A clear understanding of microscopic necrotizing vasculitis did not emerge until well into the twentieth century. Davson in 1948, and Wainwright in 1950, provided the first English language accounts of microscopic PAN or polyangiitis that affected small arterial capillaries and venules, particularly in the kidney and lungs, often associated with necrotizing glomerulonephritis [20, 21]. The neuropathologist Friedrich Wohlwill of Hamburg provided the first coherent description of microscopic necrotizing vasculitis, coining the term microscopic PAN in a description of two reported patients in 1923 [22]. Both patients described by Wohlwill [22] had antecedent illnesses characterized by weight loss, fevers, clinical evidence of nephritis, widespread muscle pain, and paresis consistent with mononeuritis multiplex. At postmortem examination, there was evidence of glomerulonephritis, and widespread inflammation of small vessels on microscopic

examination. He also described inflammatory involvement with marked polymorphonuclear cell infiltration of arterioles, capillaries and venules [22]. Wohlwill [22] conceived of a direct relationship to the disease described by Kussmaul and Maier, drawing upon his findings of systemic vascular inflammation and “a well characterized and uniform disease, which practically demand the assumption of a unified etiology [22].

In 1931, Heinz Klinger described a patient with necrotizing granulomatous vasculitis with glomerulonephritis that he considered a form of periarteritis nodosa [23]. He also described a second patient with similar findings and hemoptysis on presentation postulating a possible infectious etiopathogenesis [23]. Friedrich Wegener reported further patients which were interpreted as forms of periarteritis nodosa, however, it was clear that he viewed the disease course and related pathology as unique and anatomically distinctive particularly the invasive granulomatous process, which he believed to be due to an infectious agent [24, 25], and the granulomatous vasculitis as a form of rheumatoid or rheumatic disease [26].

In 1949, Churg and Strauss [27] described an eosinophilic form of granulomatous polyangiitis with the constellation of “allergic granulomatosis, allergic angiitis, and periarteritis nodosa. This combination of findings was previously reported by Ophüls [28] in 1923 in a patient who with granulomatous nodules, particularly of the pericardium and peritoneum with eosinophilic infiltration of the bronchi and pulmonary tissue, and concomitant arteritis, capillaritis, venulitis, and nephritis. Otani [29] also described a variant of periarteritis nodosa in 1924 in the description of a 35-year-old woman with asthma and eosinophilia. Churg and Strauss [30] provided more clinical information and systemization to the disease that eventually bore his name in a subsequent analysis of 13 patients, all of whom had asthma and granulomatous lesions in small arteries of parenchymal organs including the epicardium. These investigators [30] considered the disease to be essentially a “malignant expression” of allergic granulomatosis in contrast to other more benign forms of allergic granulomatosis such as Loeffler syndrome.

In the decades that followed, investigators provided additional clinical observations, anatomic correlations, and pathophysiologic connections between various forms of necrotizing vasculitis employing antineutrophil cytoplasmic antibodies (ANCA) that contrasted with other forms of necrotizing vasculitis. First detected in 1982 in the sera of patients with Ross River Arbovirus infection and idiopathic segmental necrotizing glomerulonephritis [31], ANCA have advanced concepts of the immunopathogenesis of necrotizing vasculitis. Subsequently detected in the sera of patients with GPA and MPA and to a lesser extent, in eosinophilic GPA (eGPA) [20], further elucidation of the role of these antibodies led to considerable advances in the understanding of the pathogenesis of systemic vasculitis [32].

Large Vessel Vasculitis

Patients with large vessel vasculitis or *pulseless disease* have been described for the past 3000 years [8]. Early descriptions of the condition were initially related to trauma while those in the late eighteenth and nineteenth centuries were causally associated with arterial sclerosis [4, 33, 34]. The formidable anatomic pathologist Morgnani [35] described an approximately 40-year-old woman with absent radial pulses for at least six years prior to her death in which

postmortem examination showed ectasia of the proximal aorta with stenosis of the lower portion, and histologically normal radial artery vessels.

In 1839, Davy [36] described two patients with likely large vessel vasculitis including a 55-year-old male who presented with weak arm pulses and later vertigo. The physical findings were of “a throbbing pulse at the upper part of the sternum, and a slight prominence of the bone there to some little extent”. Davy [36] suspected an aortic arch aneurysm, which was indeed found one and one-half years later at postmortem examination. So stated, a large aneurysm of the aortic arch was found and “all the great vessels arising from the arch were completely closed up at their origin”. Davy [36] described absent arm pulses in a 36-year-old man who like the first patient, was a soldier in the British Army. Postmortem examination in the second patient showed aortic arch dilatation and occlusion of the left subclavian and carotid arteries.

A further description from this era was given by Savory [37] in 1854 of a 22-year-old woman who was ill for five years with pulseless arteries of the arms and neck, and blindness over the ensuing year. Postmortem examination in that patient showed marked stenosis of the aortic arch and its branches, without aneurysms. Savory [37] was probably aware of the previous descriptions by Rokitsansky [15], and further differentiated his patient by ascribing the observed inflammation to an origin in the intima and media, rather than the adventitia.

It has been speculated that Ali ibn Isa [2] may have described a patient with temporal arteritis at about 1000 AD when reporting, “one treats not only migraine and headache in those patients that are subject to chronic eye disease but also acute, sharp, catarrhal affections, including those showing heat in and inflammation of the temporal muscles. These disease conditions may terminate in loss of eyesight; frequently, they are attended by a considerable degree of chemosis.” While it remains unclear whether this actually represents a case of giant cell arteritis, there is no doubt that in 1890, Hutchinson [38] provided the first clinical description of what is truly regarded as contemporary temporal arteritis when he reported a “peculiar form of Thrombotic Arteritis of the aged, which is sometimes productive of Gangrene,” in an 80-years-old man. His patient, a servant named Rumbold, presented with headache and “red streaks on his head, which were painful and prevented him from wearing his hat.” Hutchinson [38] recounted that the patient lived for several years without “any other manifestation of arterial disease.”

The clinical syndrome and histological aspects of giant cell arteritis was clearly delineated by Horton, Magath, and Brown [39] at the Mayo Clinic in 1932. Indeed, they obtained the first biopsies of the affected temporal arteries in living patients and described the typical findings including “peculiar circumscribed areas of what appear to be granulation tissue...in the adventitia of the blood vessels, which suggested granulomas,” stating further that “this represented the most characteristic lesion present.” Like Hutchinson [38], of whose work they apparently were not aware, these investigators [39] initially regarded the disease as benign, as “complete recovery occurred in each case,” however on further follow-up, they observed that two of their first patients died within two years of what they termed “unrelated conditions.” By 1938, visual loss was associated with giant cell arteritis by Jennings [40]. The association of headache with occasional jaw claudication prompted the term “cranial arteritis” in 1946 by Kilbourne and Wolffe [41].

Much earlier in 1908, Takayasu [42] described a young woman with peculiar retinal artery changes and “wreath-like anastomosis surrounding the optic disc at a distance of 2 or 3 mm, and surrounding this was another circular anastomosis”. Takayasu [42] described

“lumps” in the surrounding vessels that were seen to “move from day-to-day.” These findings were discussed at the 12th Annual Meeting of the Japanese Society of Ophthalmology whereupon other discussants noted the relation of pulseless radial arteries to the retinal artery changes in their own patients, an association that Takayasu had not appreciated [42]. By 1925, Beneke [43] reported the first comprehensive histopathologic analysis of affected large vessels in patients with pulseless disease of Takayasu arteritis type. There was virtually complete medial necrosis, intimal sclerosis, adventitial scarring and thickening of large arteries at postmortem examination in affected patients. More importantly, Beneke [43] described giant cells which he related instead atheromatous changes and white blood cell infiltrates of greater importance to the disease pathogenesis.

Other Forms of Idiopathic Vasculitis

Henoch-Schönlein Purpura

The disease known as Henoch-Schönlein purpura (HSP) likely first appeared in a report by William Heberden [44] in 1801 in the account of a 4-year-old with purpuric lesions of the leg, buttock, and scrotum; as well as in a 5-year-old with similar lesions and abdominal pain. Ollivier [4] described a youngster with purpura and abdominal pain in 1827, but the distinct disease awaited the description of “peliosis rheumatica” by Schönlein in 1837. In 1874, Henoch [46] reported four affected children with joint pain, purpuric rash, abdominal pain, and diarrhea recognizing the potentially fatal aspect of the disease. The cause of the disease has been ascribed to infection, although a specific infectious agent has yet to be definitively identified. In 1915, Frank [47] postulated an allergic cause so termed “anaphylactoid purpura”. Glanzmann [48] postulated that the combination of infection and hypersensitivity culminated in the observed findings of purpura, nephritis and abdominal pain, although a potentially causative antigen was not identified.

Behçet Disease

Oral and genital mucosal ulcers and eye inflammation of Behçet disease may have been recognized by Hippocrates but was certainly described by Blüthe [49] in 1908, Planner and Remenovskiy [50] in 1922, Shigeta [51] in 1924, and Whitwell in 1934 [52]. One of latter described patients [52], a 29-year-old woman, with oral and genital ulcers, likely erythema nodosa, and venous emboli of the leg, had the cardinal features of so-called Adamantiades-Behçet. Adamantiades [53] described a 22-year-old soldier patient with oral and genital ulcerations who experienced recurrent iritis and hypopyon, and was thought to have syphilis based on a positive Wassermann reaction. Treatment for syphilis was unsuccessful. In his initial description, Behçet [54] described two patients, a 34-year-old woman and 40-year-old man with recurrent oral and genital aphthous ulcerations, uveitis and hypopyon. Behçet [54] speculated an infectious viral cause, undertaking a detailed examination for the presence of viral products whereas a vasculitic etiopathogenesis was not contemplated.

Kawasaki Disease

In 1961, childhood febrile mucocutaneous lymph node syndrome was first described by Kawasaki [55] in Tokyo. The suspected causes included allergic, infectious, and autoimmune

mechanisms. In a subsequent report in 1974 based on more than 6000 patients seen in Japan, Kawasaki [56] indicated he noted “infantile periarteritis nodosa-like arteritis of the coronary artery accompanied by thrombosis and aneurysm...” Kawasaki disease is increasingly regarded as an infantile/juvenile form of PAN.

Single Organ Vasculitis

A multitude of single organ vasculitides has been recognized in the past several decades. Diaz-Perez and Winkelmann [57] at Mayo Clinic described a cutaneous form of PAN in 1974. A nonsystemic vasculitic neuropathy (NSVN) was described by Dyck and coworkers at the Mayo Clinic in 1986 [58]. Granulomatous angiitis (GANS), isolated angiitis of the central nervous system (IACNS) and primary angiitis of the CNS (PACNS) are equivalent terms for a potentially lethal adult CNS vasculitis, clinically and pathologically characterized beginning with the description by Cravatio and Fegin in 1959 [20, 59]. An equivalent disease affects children although curiously without granulomatous pathology. The occurrence of idiopathic vasculitis in isolated organs which has become increasingly recognized, and on occasional may evolve to affect other organs, was included in the 2012 Revised Chapel Hill Consensus Conference (CHCC) Nomenclature of Vasculitides [60]. Since the initial description by Kussmaul and Maier [14], secondary forms of vasculitis due to hypersensitivity, infection, and vasculitis occurring in the context of other autoimmune rheumatic diseases such as rheumatoid arthritis and systemic lupus erythematosus have also been described. Vasculitis has also been related to the presence of systemic cancer. Indeed, in 1958, Guichard [61] introduced the term “paraneoplastic” to describe the latter occurrence.

VASCULITIS CLASSIFICATION, NOMENCLATURE, MANAGEMENT GUIDELINE DEVELOPMENT AND RECENT ADVANCES

Early attempts to categorize the vascular diseases were based upon the likeliest etiological postulates to explain a given gross anatomical feature. Indeed, Rokitsky's [11] nineteenth century classification of aneurysms included those arising as a result of increased blood pressure and aging, non-atheromatous muscularis inflammation, trauma, pseudomembranous intimal proliferation of the intima or adventitial weakness of the intima at the site of atheroma. In 1952, Zeek [62, 6]) offered the first modern classification system of vasculitis, dividing them simplistically into hypersensitivity and angiitis, allergic granulomatous angiitis, rheumatic arteritis, periarteritis nodosa, and temporal arteritis; granulomatosis and polyangiitis and Takayasu arteritis were not included.

In 1990, the classification of vasculitis by the American College of Rheumatology (ACR) distinguished one form another based on review of nearly 1200 cases of vasculitis [64]. The 1994 [60] and 2013 Revised CHCC [65] provided better systematization and nosology, recognizing both primary idiopathic vasculitis and secondary vasculitis including those associated with hepatitis C viral infection, while foregoing the category of hypersensitivity vasculitis.

Classification criteria continue to be reexamined and revised. A major effort in this regard is the prospective enrollment of now nearly 6000 patients into the Diagnostic and Classification Criteria in Vasculitis (DCVAS) study headquartered at Oxford University and

cosponsored by the American College of Rheumatology and the European League Against Rheumatism [66]. DCVAS is a multinational, observational study that aims to develop diagnostic criteria and update classification criteria in vasculitis. DCVAS investigators have recruited over 6000 patients from 133 sites in 32 countries who have vasculitis, and vasculitis mimics.

A number of more recent contributions have made recent advances in the management of vasculitis possible and certainly will be seen in their historical context. Development of investigator cooperatives including the Vasculitis Clinical Research Consortium, the European Vasculitis Study Group, and others has greatly enhanced the ability to pursue investigation into the pathogenesis and genetics of vasculitis, as well pursuit of multicenter treatment studies. These include the advent of large scale, formal randomized trials such as the Rituximab versus Cyclophosphamide for ANCA-Associated Vasculitis (RAVE), tocilizumab in patients with Giant Cell Arteritis (GACTA), CYClophosphamide or AZathioprine As a REMission therapy for vasculitis (CYCAZAREM), and many others at the national and international level has been a major reason for improvement in vasculitis care [67, 68]. An important result of the more systematic and collaborative efforts in developing outcome measures such as the Birmingham Vasculitis Activity Score and its variants among many others [68, 69]. These approaches have are improving outcomes and lowering drug toxicity rates in patients suffering from these diseases.

Pursuit of these therapeutic studies by the various work groups has resulted in insights about how long to use cyclophosphamide, how and when to use methotrexate, azathioprine and more recently mycophenolate mofetil and other drugs in various forms of vasculitis. The studies of rituximab and other biological therapies in ANCA associated vasculitis (AAV) such as mepolizumab that targeted eosinophilic granulomatosis with polyangiitis were groundbreaking, as were later trials of biological therapy for other forms of vasculitis. These included abatacept and tocilizumab for giant cell arteritis (GCA). Such efforts led to the approval of rituximab by the Food and Drug Administration (FDA) for AAV; and tocilizumab for GCA, the latter as the first non-glucocorticoid agents ever approved by the FDA for treatment of any form of vasculitis.

Just as investigator networks have advanced the knowledge and therapeutics of vasculitis, support groups, partnerships and networks have emerged worldwide over the past three decades including, the Vasculitis Foundation in the United States, Vasculitis United Kingdom (UK), and the Arbeits-Kreis Vaskulitis in Germany. History favorably record their unique contributions in brining patients' voices to the forefront of vasculitis care and research, at the same time educating patients, families, physicians and allied healthcare providers about vasculitis.

New tests such as the ANCA (anti-neutrophil cytoplasmic autoantibodies) that came into routine use in the late 1980's and early 1990's, have been supplemented by other new tests developed in the last 30 years to more precisely image involved blood vessels and organs. These include highly sensitive magnetic resonance imaging (hsMRI); MRI and computed tomographic angiography (MRA and CTA), 2-deoxy-2-[fluorine-18]fluoro- D-glucose integrated with CT (¹⁸F-FDG PET/CT), and vascular ultrasonography techniques.

While many of the systemic vasculitides described as "idiopathic," have been discovered, some cases of PAN are also recognized to be a result of concomitant infections with hepatitis B and C virus (HBV and HCV). Likewise, a number of genes contribute to the risk for AAV and GCA and determine in part, how the diseases will affect patients [70].

CONCLUSION

The contributions of early workers in vasculitis had a profound impact in forming our modern concepts of vasculitis. They reflect careful clinical observation, the application of emerging technologies, and advances in therapy, which form the basis for our understanding of these disease entities. They are the product of an ongoing tradition of investigation, which is alive and well today. Our current knowledge of vasculitis is the result of a both long and recent history of applied clinical observation and basic science investigation. Better recognition of vasculitis in clinical practice, development of research networks and patient involvement in vasculitis care, improved imaging modalities, outcome measure development, and application of novel therapeutics based upon better understanding of disease pathogenesis have also led to better effective treatment of vasculitis.

ABSTRACT

The systemic vasculitides are heterogeneous clinicopathologic disorders that share the common feature of vascular inflammation. The resulting disorder can vary depending upon involvement of specific organs, caliber of blood vessels, the underlying inflammatory process, and individual host factors. The cumulative result is diminished blood flow, vascular alterations and eventual occlusion with variable ischemia, necrosis and tissue damage. An international revised nomenclature system based on the current state of knowledge provides clinicians and investigators alike with the necessary nosology and findings relevant to classify each of the vasculitides. This chapter is an introduction and overview of the clinical presentation, differential diagnosis, laboratory evaluation, and treatment of systemic and nervous system vasculitides.

INTRODUCTION

The term vasculitides refers to heterogeneous disorders characterized by vascular inflammation affecting vessels of different sizes from large arteries to capillaries or tiny venules. This leads to diminished blood flow or vessel occlusion resulting in ischemia,

* Corresponding Author's Emails: david.younger@nyumc.org; <http://www.davidsyounger.com>.

necrosis and subsequent tissue damage. Blood vessels themselves can also be damaged in vasculitis resulting in permanent stenosis, aneurysmal change or rupture.

CLASSIFICATION AND NOSOLOGY

The 2012 Revised Chapel Hill Consensus Conference (CHCC) [1] serves as a guide for the categorization of diverse forms of vasculitis based upon the vessels involved (Table 1).

Large vessel vasculitis (LVV) including giant cell arteritis (GCA) and Takayasu arteritis (TAK) affects the aorta, its major branches and analogous veins. Medium vessel vasculitis (MVV) inclusive of polyarteritis nodosa (PAN) and Kawasaki disease (KD) involves main visceral arteries and veins and initial branches. Small vessel vasculitic (SVV) involvement affects intraparenchymal arteries, arterioles, capillaries, veins and venules, with a disease mechanisms related to anti-neutrophil cytoplasmic antibody (ANCA) or immune complexes.

Table 1. Classification of vasculitides

Large Vessel Vasculitis
Giant cell arteritis
Takayasu arteritis
Medium Vessel Vasculitis
Polyarteritis nodosa
Kawasaki disease
Small Vessel Vasculitis
<i>ANCA-Associated Vasculitis</i>
Microscopic polyangiitis
Granulomatosis with polyangiitis (Wegener)
Eosinophilic granulomatosis with polyangiitis (Churg-Strauss)
<i>Immune-Complex Vasculitis</i>
Cryoglobulinemia
IgA vasculitis (Henoch-Schönlein)
Hypocomplementemic urticarial vasculitis (anti-C1q)
Variable Vessel Vasculitis
Behçet disease
Cogan syndrome
Single Organ Vasculitis
Primary Angiitis of the CNS
Nonsystemic peripheral nerve vasculitis
Idiopathic aortitis (IgG4)
Vasculitis Associated with Systemic Collagen Vascular Disease
Systemic lupus erythematosus
Rheumatoid arthritis vasculitis
Vasculitis Associated with Infection
Acute bacterial meningitis
Tuberculous meningitis
Spirochete disease
Neurosyphilis
Lyme neuroborreliosis
Varicella zoster virus
HIV/AIDS

Adapted from [1].

The category of ANCA-associated vasculitis (AAV) includes granulomatosis with polyangiitis (GPA) (Wegener granulomatosis [WG type]), eosinophilic granulomatosis with polyangiitis (EGPA) (Churg-Strauss syndrome [CSS]), and microscopic polyangiitis (MPA) (microscopic polyarteritis), while vasculitic disorders associated with immune complexes (IC) includes IgA vasculitis (IgAV) (Henoch-Schönlein purpura [HSP]), cryoglobulinemic vasculitis (CV), and Hypocomplementemic urticarial vasculitis (HUV) associated with C1q antibodies. Vasculitis without a predominant vessel size and caliber, respectively from small to large, involving arteries, veins and capillaries, comprises the category of variable vessel vasculitis (VSV), characteristic of Behçet disease (BD) and Cogan syndrome. Vascular inflammation confirmed to a single organ system such as vasculitis restricted to the central nervous system (CNS) and peripheral nervous system (PNS), and IgG4 related aortitis (IgG4-related disease [RD]), are collectively referred to as single organ vasculitides (SOV).

There is a separate category for vasculitis associated with systemic disease notably for connective tissue disorders such as rheumatoid arthritis vasculitis (RAV) and systemic lupus erythematosus (SLE); and another for vasculitis associated with a probable specific etiology, such as substance abuse and infection designated by the specific vasculitic disorder with a prefix to denote the causative agent.

In 2008, the Pediatric Rheumatology European Society (PRES) and the European League against Rheumatism (EULAR) and the Pediatric Rheumatology International Trials Organization (PRINTO) reported methodology and overall clinical, laboratory and radiographic characteristics for several childhood systemic vasculitides [2] followed by a final validated classification [3] based upon vessel size, similar to the CHCC nomenclature [1].

Insight into effective therapies of systemic vasculitides have been guided by collaborative evidence-based randomized clinical trials (RCT) or observational cohorts by the French Vasculitis Study Group (FVSG) database, United States-Canadian Vasculitis Clinical Research Consortium (VCRC), European Vasculitis Study Society (EUVAS), the European League Against Rheumatism (EULAR), The French Vasculitis Cohort of Patients with Primary Vasculitis of the Central Nervous System (COVAC), Diagnostic and Classification Criteria in Vasculitis Study (DCVAS), the Pediatric Vasculitis Initiative (PedVas), the Diagnostic and Classification Criteria in Vasculitis Study (DCVAS), and the web-based network BrainWorks.

Despite disparities in vessel involvement and end-organ damage, it is usually possible to reach a presumptive diagnosis of primary and secondary vasculitides in the majority of patients based upon the combination of presenting symptoms and signs, disease-specific serological studies, and visceral and neurovascular imaging studies, while awaiting the results of tissue histopathology.

This chapter is an overview of primary and secondary vasculitides in adults and children for clinicians treating such patients. Five major challenges encountered in clinical practice will be addressed and emphasized as follows.

First, clinical, pathological, and serological differentiation and diagnosis of the primary vasculitides including LSV (GCA, TAK), MVS (PAN, KD), SVS (AAV [MPA, GPA, EGPA] and IC-mediated types [IgAV and anti-C1q]); and VSV (BD and Cogan syndrome), all of which share demonstrable histopathological evidence of systemic vasculitis.

Second, recognition of secondary vasculitides associated with an underlying primary systemic illness, in which some but not all patients will demonstrate evidence of vasculitis

including, CV, RA vasculitis (RAV), and CNS vasculitis associated with SLE, syphilis, Lyme neuroborreliosis (LNB); bacterial meningitis, tuberculosis (TB), varicella zoster virus (VZV), and human immunodeficiency virus type 1 (HIV) and acquired immune deficiency syndrome (AIDS).

Third, the identification of the SOV, PCNSA, NSPNV, and IgG4-RD.

Fourth, a recommended laboratory approach to the diagnosis of vasculitides.

Fifth and last, evidence-based treatment options for each of the vasculitides. Interested readers are recommended to another in-depth overview [4].

DIFFERENTIATION OF PRIMARY VASCULITIDES

Large Vessel Vasculitides

The concepts of GCA and TAK have evolved over a century, with considerable advances in the past decade that have translated into more improved diagnosis and management.

Giant Cell Arteritis

First named temporal arteritis for the site of granulomatous giant cell inflammation and vessel involvement [5], those with associated blindness due to vasculitic involvement of ophthalmic and posterior ciliary vessels were subsequently classified as cranial arteritis [6], and later generalized GCA [7] when giant cell lesions were discerned along the aorta, its branches, and in other medium- and large-sized arteries at postmortem examination. There are five discriminatory features of GCA including, age >50 years at onset, new localized headache, temporal artery tenderness or decreased temporal artery pulse, ESR >50 mm/hour, and biopsy of an artery showing necrotizing arteritis and a predominance of mononuclear cells or granulomatous process with multinucleated giant cells (Figure 1), that collectively serve as useful guideposts in recognizing GCA.

Unrecognized and therefore untreated or inadequately treated, there is a high likelihood of large artery complication. Nuenninghoff and coworkers [8] reported patients with large-artery complications representing 27% of 168 patients in a GCA cohort at the Mayo Clinic between 1950 and 1999 that included aortic aneurysm or dissection in 18%, large artery stenosis in 13%, cervical artery stenosis in 9%; and subclavian, axillary or brachial artery stenosis in 4%.

Temporal artery biopsy is the only sure way of establishing the diagnosis however false negative findings on the contemplated affected side may be due to inadvertent sampling of a vasculitic-free length of vessel. The pathological heterogeneity of GCA was further exemplified by the occasional finding of intracranial lesions in several patients who also qualified for the diagnosis of granulomatous angiitis of the nervous system (GANS) [9]; however PNS involvement in GCA remains exceedingly uncommon [10].

Takayasu Arteritis

Contemporaneously, another LVV was described in the Japanese literature as unusual changes of the central vessels of the retina in the absence of peripheral arterial pulses in women [11]. Patients with so called pulseless disease [12], occlusive thromboangiopathy [13]

or TAK [14], manifested constitutional complaints of malaise, fever, stiffness of the shoulders, nausea, vomiting, night sweats, anorexia, weight loss, and irregularity of menstrual periods weeks to months before the local signs of vasculitis were recognized in up to two-thirds of patients. TAK is the commonest large vessel vasculitis among Asian women.

The non-invasive assessment of LVV includes performance of color-Doppler sonography (CDS), contrast enhanced high-resolution magnetic resonance imaging (MRI) combined with MRA, and contrast-enhanced computed tomography (CT) combined with CTA to visualize the vessel wall and the lumen of large vessels. The signs of early inflammation that include vessel wall thickening and mural inflammation, as well as the late complications of stenosis and aneurysms, can be ascertained.

Figure 1. Giant cell arteritis. (A) An early lesion of a large muscular artery, necrosis, inflammation, and giant cell formation (single arrow) can be seen immediately adjacent to the internal elastic lamina (arrowhead), which is undergoing degenerative changes, and there is some intimal proliferation (double arrows) (stain, hematoxylin and eosin; original magnification, $\times 100$). (B) This more advanced lesion has complete segmental destruction of the internal elastic lamina and virtually the entire media (arrows). Marked intimal proliferation has nearly occluded the lumen, and few inflammatory cells remain (stain, hematoxylin and eosin; original magnification, $\times 50$).

^{18}F - Fluorodeoxyglucose (FDG) positron emission tomography (PET) detects increased FDG uptake by metabolically active cells, including inflammatory cells infiltrating the vessel wall in vasculitis, while digital subtraction angiography (DSA) is a useful modality to

demonstrate luminal changes. Moreover, such studies can assist the surgeon in centering on an involved segment of vessel. Performance of CDS is better suited to study superficial vessels such as the internal and external carotid artery and its branches, while MR and CT are best suited for deep vessels. When performed together, they can be used to monitor disease extent and severity through the demonstration of early vascular changes in wall thickness and mural inflammation, to which PET can be added to ascertain active inflammation in vessels affected by GCA and TAK. Since the early reports of a salutary effect of corticosteroids on GCA in 1950 [15], corticosteroids have remained the standard of care because of their ability to reduce disease-related morbidity, mortality, and symptoms that negatively impact on quality of life. However they are not curative, do not prevent relapses, and are associated with significant toxicity. Disease-related morbidity in GCA which largely results from cranial ischemic events or LVV, leads to visual loss in up to 20% of patients.

The risk factors for GCA-related ischemic events include visual loss, prior ischemic events, marked intimal hyperplasia on temporal artery biopsy, elevated inflammatory markers, older age at diagnosis, hypertension, ischemic heart disease, and absence of systemic manifestations [16]. While there is no treatment to date that has been found to completely reverse blindness in GCA once it has occurred, there is strong evidence to suggest that once corticosteroids have been started the risk of visual loss is low [17]. For this reason, corticosteroids should be started while the diagnostic evaluation is in progress and continued for up to one year before tapering to the lowest maintenance levels.

Ohigashi and colleagues [18] ascertained an improved prognosis among 106 consecutive patients with TAK in those with onset before 1999 compared to those diagnosed after 2000 (4.2% versus 0%) that was attributed to reduction in the time from onset to diagnosis, replacement of digital subtraction angiography (79% versus 9%) with ultrasound (6% versus 34%), CTA (24% versus 77%), MRA (21% versus 57%), and ¹⁸F-FDG PET (0% versus 20%); less frequent complications of moderate or severe aortic regurgitation, and not surprisingly, an increase in the use and maximal dose of corticosteroids (70% versus 97%); and the use of first and second-line immunosuppressant agents (7% versus 42%). Surgical treatment of TKA was similar between those with onset before 1999 and after 2000 (22.5% versus 22.8%).

Medium Vessel Vasculitides

Polyarteritis Nodosa and Kawasaki Disease

Kernohan and Woltman [19] summarized the clinicopathological aspects of adult PAN at postmortem examination, while Krahulik and colleagues [20] described fulminant childhood PAN (cPAN), three decades after the first description of the first American patient by Longcope in 1908 [21]. The dominant clinicopathological syndrome was peripheral neuritis that occurred in one-half of patients early in the illness with a predilection for the legs. The combination of acute and chronic lesions correlated with known exacerbations. Arteritic lesions along nutrient arteries of the peripheral nerves were characterized by invasion of the intima, media and adventitia by polymorphonuclear, plasma cells, eosinophils, and lymphocytes associated with swelling of the media, fibrinoid necrosis, and fragmentation of the internal elastic lamina (Figure 2). So impressed was Dr. Harry Lee Parker by the

frequency of arteritic lesions in the PNS, that he conceptualized nerve and muscle biopsy as a useful mode for the diagnosis in life during a discussion of the paper by Kernohan and Woltman [19]. Variants of cPAN were contemporaneously recognized in infants and young children under the rubric of mucocutaneous lymph node syndrome, infantile PAN before arrival at the preferred term KD [22-25] for the childhood syndrome affecting children of all ages and races, with worldwide occurrence.

A retrospective study of 348 adult patients registered in the French Vasculitis Study Group (FVSG) [26] who satisfied criteria for the diagnosis of PAN between 1963 and 2005 noted constitutional findings included fever, weight loss, myalgia, and arthralgia at presentation in 93% of patients. PNS involvement included peripheral neuropathy and mononeuritis multiplex in nearly equal proportion in 79%, and cutaneous involvement notably, purpura, skin nodules, and livedo reticularis were noted in 50% of patients; CNS involvement was noted in 5% of patients.

Source: Reproduced from reference [4], with permission.

Figure 2. This small muscular artery from muscle is from a patient with polyarteritis nodosa. In the third, or proliferative, phase illustrated here, chronic inflammatory cells replace the neutrophils of the second phase; there is evidence of necrosis of the media (arrows), early intimal proliferation (arrowheads), and fibrosis. The lumen is almost completely occluded. Ultimately, in the healing phase, this process is replaced by dense, organized connective tissue (stain, hematoxylin and eosin; original magnification, $\times 250$).

The classification criteria for cPAN requires histological evidence of necrotizing vasculitis in medium-or small-sized arteries or angiographic abnormalities demonstrating aneurysm formation or vascular occlusions, as a mandatory criterion, plus two of five features among them myalgia, skin involvement, hypertension, neuropathy, or abnormal urinalysis or impaired renal function [6], with disease manifestations ranging from a benign cutaneous form with clinical, laboratory and molecular characteristics of Familial Mediterranean Fever [27, 28] to severe disseminated multisystem disease. Ozen and colleagues [29] studied 110 children of mean age 9 years, from twenty-one pediatric centers worldwide diagnosed with cPAN dividing them into four groups including systemic PAN (57%), cutaneous PAN (30%), and classic PAN with hepatitis B surface antigen (HBsAg) (4.6%). Children with serological and microbiologic evidence of preceding streptococcal infection have also been described [30]. The FVSG study [26] allowed for a comparison of diagnostic modalities in adult PAN.

Only 6 of 47 sera so tested manifested a positive ANCA finding by immunofluorescent testing (IFT) and enzyme linked immunosorbant assay (ELISA) techniques, rendering it helpful in support of PAN especially when negative to differentiate it from AAV and MPA. Cutaneous nerve biopsy performed in 129 patients, including 108 with peripheral neuropathy and 21 without peripheral neuropathy, showed typical vasculitic lesions respectively in 83% and 81%, compared to muscle biopsy that revealed vasculitis respectively in 68% and 60% of patients. Angiography showed renal and gastrointestinal microaneurysms or stenosis respectively in 66% and 57% of patients. Patients with HB virus (HBV)-related PAN had more frequent peripheral neuropathy, abdominal pain, cardiomyopathy, orchitis, and hypertension than those with non-HBV-related PAN, with respective five-year relapse-free survival rates of 59% and 67% in scheduled therapeutic regimens depending upon involvement in clinical trials, or according to the standard of care at the time of diagnosis, among them glucocorticoids and cyclophosphamide [31, 32]. The predictors of a poor prognosis were age >65 years, hypertension, and gastrointestinal involvement, and cutaneous manifestations or non-HBV-related PAN had higher rates of relapse.

Henegar and colleagues [33] identified three positive predictive parameters including HBV antigen and DNA in serum, arteriographic anomalies, and mononeuropathy or polyneuropathy; and five negative predictive parameters including detection of ANCA; asthma, ear, nose and throat signs; glomerulopathy; and cryoglobulinemia, that yielded a 70.6% sensitivity for control vasculitides and 92.3% specificity for all controls.

Small Vessel Vasculitides

ANCA-Associated Vasculitis

Microscopic Polyangiitis

Wohlwill [34], Davson and colleagues [35] and Wainwright and Davson [36] recognized that fever, arthralgia, purpura, hemoptysis, pulmonary hemorrhage, abdominal pain, and gastrointestinal bleeding preceded the explosive phase of systemic necrotizing vasculitis in some patients with a disorder other than PAN that affected the kidney and lungs, with rapidly progressive glomerulonephritis and pulmonary capillaritis. Such patients with selective involvement of small microscopic arteries, arterioles, capillaries and venules including glomerular and pulmonary alveolar capillaries were deemed to have microscopic PAN. Among thirty-four such patients described by Savage and colleagues [37] the clinical symptoms and signs at presentation were constitutional (67%), arthralgia (65%), purpura (44%), hemoptysis in (32%), abdominal pain (32%), mouth ulcers (21%), sensory peripheral neuropathy (18%), and CNS (headache, seizures) (18%). Eighty-five additional patients studied by Guillevin and colleagues [38] with MPA so termed, had renal involvement (79%), weight loss (73%), skin involvement (purpura, livedo, nodules, urticarial) (62%), mononeuritis multiplex neuropathy (57%), fever (55%), arthralgia (50%), myalgia (48%), vascular manifestations [hypertension, cardiac failure, pericarditis] 50%, lung involvement (alveolar hemorrhage, pneumonitis, pleurisies) (24%), and CNS involvement (12%). Ahn and colleagues [39] noted pANCA or anti-MPO antibody positivity in 69% of Korean MPA patients, compared to 74.5% of positive ANCA in European patients, of whom 87% had a

pANCA staining pattern. Antibodies to PR3 were present in 8% of patients compared to MPO in 61% of those as determined by ELISA. Childhood MPA (cMPA) appears to be very uncommon and the criteria for diagnosis require three of the following features to be present: abnormal urinalysis, granulomatous inflammation on tissue biopsy, nasal sinus inflammation; subglottic, tracheal, or endobronchial stenosis; abnormal chest radiograph or chest CT scan, and PR3 ANCA or cANCA staining [3]. Those with cMPA accounted for four of the first 32 children in the United States/Canadian ARChiVe registry [40].

Eosinophilic Granulomatosis with Polyangiitis

Contemporaneous with the description of MPA, the first patient with EGPA was probably Case 1 of Lamb [41] reported in 1914 also under the heading of PAN. That patient, a 26-year-old man with two years of worsening asthma, developed fever, palpable purpura, nodular skin lesions, hemoptysis, vomiting, urinary difficulty and granular urinary casts. He died one month later and postmortem examination showed necrotizing arteritis of small arteries, with dense collections of extravascular eosinophils and tissue eosinophilia in the heart, stomach, and kidney. Decades later, Churg and Strauss [42] described the clinical and postmortem findings of thirteen patients with asthma, fever, and hypereosinophilia, accompanied by eosinophilic exudation, fibrinoid change, and granulomatous proliferation or the so called allergic granuloma. The latter was found within vessels walls and in extravascular connective tissue of major organ systems, leading to cardiac, pulmonary, gastrointestinal, skin, PNS and CNS manifestations. In 1990, the American College of Rheumatology (ACR) [43] developed criteria for the classification of EGPA that included ascertainment of four or more of the following: asthma, eosinophilia of >10%, mononeuropathy or polyneuropathy, non-fixed pulmonary infiltrates on chest radiograph, paranasal sinus abnormality, and extravascular eosinophils on tissue biopsy that included an artery, arteriole or venule. These criteria were inadequate since a patient with asthma and paranasal sinusitis could also fit the designation of EGPA. The 1994 CHCC [1] characterized EGPA as an eosinophil-rich and granulomatous inflammatory process that involved the respiratory tract, with necrotizing vasculitis that affected small to medium-sized vessels such as capillaries, venules, arterioles and arteries, with associated asthma and eosinophilia. Among 383 patients enrolled in the FVSG Cohort [44] who satisfied the ACR criteria [43] or in 1994 CHCC definition for EGPA [45], the mean age at presentation was 50 years without sex predominance. Clinical manifestations at presentation included asthma (91%), peripheral neuropathy (51%), weight loss (49%), ear, nose and throat signs (48%), non-erosive sinusitis and polyposis (41%), skin lesions (39%), purpuric rash (22%), lung infiltrates (38%), gastrointestinal involvement (23%), renal manifestations (22%), cardiomyopathy (16%), CNS (5%), and cranial nerve involvement (3%). A total of 108 (31%) patients tested positive for ANCA with significantly more frequent ear, nose and throat, peripheral nerve and renal involvement, but less frequent cardiac manifestations. Small numbers of children have been included in large studies of EGPA sufficient to allow comparisons to adults. Among 133 vasculitic patients in the ARChiVe registry, only two were reported to be of the EGPA type [46].

Granulomatosis with Polyangiitis

Godman and Churg [47] described the syndrome of GPA that included granuloma in the nasopharynx, sinuses and lower respiratory tract with focal segmental glomerulonephritis and

disseminated small vessel vasculitis. In a landmark article, Godman and Churg [47] concluded that MPA, EGRA and GPA were related to one another yet distinct from PAN. This astute conclusion was based mainly on pathological features was later substantiated by their common association with ANCA, but not so for PAN [48]. Fauci and colleagues [49] and Hoffman and colleagues [50] at the National Institutes of Health (NIH), respectively reported a prospective series of eighty-five patients with GPA, and a retrospective assessment of 180 patients followed for 6 months to 24 years. The presenting signs included pulmonary infiltrates (71%), sinusitis (67%), arthritis and arthralgia (44%), fever (34%), cough (34%), otitis (25%), and hemoptysis (22%), with an overall predominance of organ system involvement in the lung (94%), paranasal sinuses (91%), kidney (85%), joints (67%), and nasopharynx and nose (64%). Fauci and colleagues [49] established the efficacy of cyclophosphamide and prednisone in achieving complete remissions in 93% of patients, as well as, the tendency of patients to relapse and accrue additive mortality from both disease and treatment. The characteristic histopathology is a necrotizing granulomatous vasculitis which may be found in lung and renal biopsy tissue although the latter is less common. Instead, a focal, segmental glomerulonephritis is often seen. Other inflammatory or vasculitic phenomenon can be encountered such as leukocytoclastic vasculitis in skin lesions, and acute and chronic inflammation in sinus, retro-orbital, and tracheal tissues. A limited form of GPA without glomerulonephritis was described [51] that was a long-term disease stage or phenotype accounting for about 5% of all patients characterized by destructive and space-consuming lesions associated with relapse rates of 46% and local damage [52].

The 1990 ACR criteria for the classification of GPA [53] which preceded routine ANCA testing, included the presence of two or more from criteria from among four including nasal or oral inflammation (painful or painless oral ulcers or purulent or bloody nasal discharge); abnormal chest radiograph (showing nodules, fixed infiltrates or cavities); urinary sediment (showing microhematuria >5 red blood cells per high power field, or red cell casts in urinary sediment); and granulomatous inflammation on biopsy tissue (within the wall of an artery or in the perivascular or extravascular area of an artery or arteriole).

A proposed classification tree substituted hemoptysis for granulomatous inflammation on a tissue biopsy if the latter was not available. Baseline serum samples for 180 participants in the WG Etanercept Trial Research Group (WGET) found that when IF, direct and capture ELISA ANCA testing were performed at baseline, 166 (92%) were seropositive, including 96% with severe disease and 83% with limited disease.

Holle and colleagues [54] who prospectively compared a highly sensitivity (hs)PR3-ANCA ELISA to the IFT noting an excellent performance of the hsPR3-ANCA ELISA in identifying GPA and other AAV disorders associated with PR3-ANCA suggesting that the former by used as screening test. Since the early observations of ANCA provided by van der Woude and colleagues in 1985 [55], and Falk and Jennette [56] and Goldschmeding and colleagues [57], and ensuing progress in the differentiation and understanding of ANCA subtypes [58], the past quarter century has witnessed a renaissance in the understanding of primary systemic vasculitis with convincing clinical evidence to support an important role for ANCA in the development of AAV. An AAV classification appears to better recognize ANCA disease and predict prognosis than other any existing clinical classification systems [59].

However as with other autoimmune disorders, the etiology and pathogenesis appears to be multifactorial, involving the interplay of initiating and predisposing environment and

genetic factors [60-62]. Induction with corticosteroids and either cyclophosphamide followed by maintenance with rituximab [63-68] or azathioprine [69-71] is recommended treatment. Among 197 ANCA-positive patients with GPA or MPA in nine centers participating in the Rituximab in ANCA-Associated Vasculitis-Immune Tolerance Network (RAVE-ITN), a randomized, double-blind, double-dummy, non-inferiority trial [72] comparing rituximab 375 mg per square meter (m²) body-surface area (BSA) per week for 4 weeks to cyclophosphamide 2 mg per kilogram of body weight per day controls for severe AAV, 67% of study patients compared to 42% of controls achieved the primary end point of remission of disease without use of prednisone at six months.

Treatment and efficacy and safety data in children with AAV continue to be largely derived from adult GPA studies, however as described in ARChive, pediatric patients in the United States and Canada are being offered pulse methylprednisolone for 3 to 5 days, followed by oral prednisone, and cyclophosphamide orally or with one of two intravenous regimens, followed by maintenance therapy, most frequently with methotrexate [40].

Early outcome results last year for the treatment of childhood AAV, in particular GPA, reported by Morishita and colleagues on behalf of ARChive Investigators Network and the Pediatric Vasculitis (PedVas) Initiative [73] was somewhat unencouraging. Among 105 children with AAV, mainly GPA, who received corticosteroids, cyclophosphamide, methotrexate, or rituximab for remission-induction, and plasma exchange in conjunction with cyclophosphamide and/or rituximab, 42% achieved remission at 12 months (Pediatric Vasculitis Activity Score [PVAS] of 0, CS dose < 0.2 mg/kg/day), 21 (48%) of whom discontinued CS by 12 months; all but 3 remaining on maintenance treatment at 12 months receiving azathioprine, methotrexate, rituximab, mycophenolate mofetil, and cyclophosphamide. However, up to 63% had a (Pediatric Vasculitis Damage Index [PVDI]) score of 1 or more by 12 months, with the presence of renal, ear, nose and throat, or pulmonary damage; moreover, 41% of children reported hospitalizations. Thus, a significant proportion of patients were not in remission at 12 months, and more than one-half of the patient cohort experienced damage early in the disease course. The 12-month remission rate of 42% in the cohort was significantly lower than Sacri and colleagues [74] who reported 73% remission at post-induction and 90% overall remission rate (including secondary remissions after a median time of 6.7 months).

Immune Complex Vasculitis

The foundations for IC-mediated or hypersensitivity vasculitis were conceptualized in the mid-twentieth century, as an immunologic response to antigenic material associated with clinically evident purpura, and small vessel inflammation affecting arterioles, capillaries, and post-capillary venules. It was likened by Zeek [75] to the anaphylactoid Arthus reaction produced by the experimental injection of horse serum into rabbits [76].

IgA Vasculitis (Henoch-Schönlein Purpura)

Children with HSP were described by Gairdner [77] with anaphylactoid purpura including one who developed rash, colic, melanotic stools, intussusception, and hematuria following by a typical exanthema and fatal convulsion. Postmortem examination showed

scattered cortical hemorrhages associated with cerebral necrotizing arteriolitis. Levitt and Burbank [78] described the clinicopathological findings in two previously non-allergic patients with recurrent fatal attacks of HSP after injection of penicillin and ingestion of strawberries respectively that included glomerulonephritis alone or with systemic arteriolitis. The findings of IgA deposits in cutaneous blood vessel walls and in glomerular mesangial biopsies of patients with HSP and IgA nephropathy (IgAN) [79, 80] were circumstantially convincing enough to substitute the term IgAV for HSP. IgAV/HSP is the commonest vasculitis in children. The 1990 ACR criteria [81] for the identification of HSP included age less than or equal to 20 years at disease onset, palpable purpura, acute abdominal pain, and tissue biopsy showing granulocytes in the walls of small arteries or venules. The presence of any two or more of these criteria distinguished 85 patients who were diagnosed as having HSP by physicians who submitted cases for the vasculitis criteria compared to 722 patients diagnosed with other forms of vasculitis, arriving at sensitivity of 87.1% and specificity of 87.7%. The addition of gastrointestinal bleeding in a classification tree format respectively increased sensitivity to 89.4% and specificity to 88.1%. The EULAR/PRINTO/PReS classification criteria [3] which recognizes the contribution of IgA deposits, differs in the mandatory finding of purpura with predominance in the legs, and the presence of one of the four following features: diffuse abdominal pain, arthralgia or arthritis; a biopsy showing predominant IgA deposits, and renal involvement including proteinuria and hematuria. Derived from the analysis of 827 patients in the database, the calculated sensitivity, specificity for the clinical and laboratory findings in between the consensus panel and specific definition were respectively 100% and 87%. Peru and colleagues [82] studied 254 children with IgAV/HSP between 2003 and 2006 with a distribution of skin, joint, GI and renal manifestations respectively of 100%, 66%, 56% and 30%. The disorder commences with fever and palpable purpura, although early lesions can be urticarial. Arthralgia and abdominal pain precede, accompany or follow the rash. Melena is common as are signs of peritonitis. Proteinuria and hematuria are of variably severity and renal pathology may be of a mild glomerulitis to necrotizing or proliferative glomerulonephritis. Ozen and coworkers [3] noted palpable purpura, commonly in crops with lower limb predominance in 89% of patients, arthritis or arthralgia in 78%, diffuse abdominal pain in 60%, proteinuria and hematuria combined in 33%; and IgA deposition in 10% of children. The treatment of IgAV/HSP remains empiric and largely supportive, with conflicting conclusions in retrospective and uncontrolled case series of immune suppression in severe HSP nephritis [46]. Extrarenal manifestations can be managed by symptomatic treatment.

A meta-analysis of 15 studies based on a comprehensive review of the literature in the Medline database from 1956 to 2007, and Cochrane Controlled Trials Registry among 15 studies and over 1300 patients [46] found that early treatment conferred a protective effect on developing persistent renal disease (odds ratio [OR] .43) and the likelihood of surgical intervention for abdominal pain (OR .75), as well as a statistically significant positive effect on shortening the duration of abdominal symptoms (OR 5.42).

C1q (Hypocomplementemic Urticarial) Vasculitis

McDuffe and colleagues [83] later described several patients with recurrent attacks of erythematous, urticarial, and hemorrhagic skin lesions that lasted 24 hours at a time, associated with recurrent attacks of fever, joint swelling, abdominal distress, and depressed serum complement. When tested by immunodiffusion against purified preparations RF and

human C1q, several patients reacted strongly with purified C1q. Skin biopsies showed leukocytoclasia, characteristic of necrotizing vasculitis, anaphylactoid purpura, or mild nonspecific perivascular infiltration. Immunofluorescence of skin specimens showed fixation of Ig in the patient with necrotizing vasculitis. Renal biopsy showed mild to moderate glomerulonephritis indistinguishable for those seen in other forms of chronic membranoproliferative glomerulonephritis. The differences from SLE included more urticarial and purpuric skin lesions, with relatively mild renal or absent and other visceral involvement in the patients with HUV. An etiopathogenesis related to chronic vascular inflammation resulting from deposits of immune complexes in small vessel walls seemed likely. Zeiss and colleagues [84] characterized C1q IgG precipitins from HUV sera that precipitated C1q in agarose gel among four additional patients. Wisnieski and Naff [85] later showed C1q binding activity in IgG from HUV sera. Buck and colleagues [86] defined the HUV syndrome as the presence of UV with multi-organ involvement notably arthralgia or arthritis, angioedema, pulmonary, ocular, renal, and pericardial. However, anti-C1q antibodies are elevated and the serum low C1q levels are reduced in virtually all children so studied. Antihistamines are the drug of choice with cutaneous lesions to control itching, but they may be insufficient in controlling the formation of immune complexes when given late in the inflammatory cascade. There is yet a consensus on the most effective therapeutic regimen; however plasmapheresis and intravenous immune globulin (IVIg) are alternative immunosuppressant modalities.

Variable Vessel Vasculitis

Behçet Disease

Behçet [87] described the clinicopathological findings of a 28-year-old Turkish patient with relapsing oral, genital and oral eruptions over 4 years, accompanied by severe headache, memory loss, dizziness, lethargy, fatal seizures and coma. Postmortem examination showed perivascular inflammatory cell infiltration of the meninges, brain, and central retinal artery and optic nerve with necrotic cerebral lesions. The first well-documented American patient with nervous system involvement of BD was described by Wolf and coworkers [88], namely a 22-year-old woman with a five year history of recurrent oral and genital ulceration, and a two year course of progressive visual loss, headache, hemiparesis, ataxia, tremor, dysarthria, cranial nerve palsy, cerebellar and corticospinal tract disease, and mental deterioration, which responded to prednisone therapy. The most widely used diagnostic criteria of BD were formulated by the International Study Group (ISG) [89] that included recurrent oral ulcerations plus any two of genital ulceration, typical defined eye lesions, typical skin lesions, or a positive pathergy. Recurrent oral ulcerations were categorized as minor aphthous, major aphthous, and herpetiform ulcerations that recurred at least three times in a 12-month period. Recurrent genital ulcerations were defined as aphthous ulceration and scarring. Eye lesions were defined as anterior uveitis, posterior uveitis or cells in the vitreous on slit lamp examination; and retinal vasculitis. Compatible skin lesions included erythema nodosum, pseudofolliculitis, papulopustular lesions, and acneiform nodules in post-adolescent patients not receiving corticosteroids. A positive pathergy test of cutaneous hypersensitivity was defined as positive when a sterile pustule developed after twenty four to forty-eight hours at

the site of a needle prick to the skin [90]. Although the usual onset of BD is in the third or fourth decade of life, pediatric-onset patients have been described [91]. The neuropathological findings in BD in brain biopsies and postmortem examination have been remarkably consistent among patients over the past several decades evidencing perivascular cuffing of small meningovascular and parenchymal arteries and veins, rarely medium-sized arteries displaying fibrinoid degeneration and recanalization, and examples of venous thrombosis. Cortical venous sinus thrombosis (CVST) [92] in BD presents with subacute or chronic onset of symptoms of isolated intracranial hypertension accompanied by headache, blurred vision, and diplopia [93], and underlying necrotizing vasculitis. Venous infarcts occur in up to 63% of those with CVST of other causes, but in only 6% of patients with BD. The inflammatory cell infiltrates are generally comprised of lymphocytes, both T-, and B-cells, macrophages, rarely plasma cells and eosinophils, with reactive astrocytosis and microscopic gliosis in neighboring cerebral, cerebellar and brainstem white matter. Matsumoto and colleagues [94] noted large vessel lesions in seven of eight patients age 31 to 56 years with BD, including saccular aneurysms of the sinus of Valsalva or aortic arch, thoracic and abdominal aorta, pulmonary, femoral, and iliac arteries, and thrombotic occlusions in the pulmonary vein and superior and inferior vena. Aortitis was noted histologically in six of the eight patients that was active in one, scarred in six, and intermixed in another. Active aortitis was characterized by intense infiltration of inflammatory cells in the media and adventitia more frequently than in the interim with occasional giant cell formation. Although anticoagulation would not be recommended for BD-related CVST, it might be considered in association with arterial occlusions, with both venous and arterial occlusive episodes warranting prompt consideration of corticosteroids alone or in association with another immunosuppressant agent.

Cogan Syndrome

The first patient with Cogan syndrome of non-syphilitic interstitial keratitis (IK) was reported by Mogan and Baumgartner [95], that of a 26-year-old man with recurrent pain, spasm and redness of the left eye with photophobia, excessive tearing, and marked conjunctival injection, followed by severe attack of dizziness, tinnitus, vertigo, nausea, vomiting, ringing in the ears, profuse perspiration, and deafness. A diagnosis of recurrent interstitial keratitis and explosive Menière disease was made. Vestibuloauditory symptoms were later described by Cogan [96]. Haynes and colleagues [97] set forth diagnostic criteria for typical Cogan syndrome according to the definitions established in a review of 30 patients seen at the National Eye Institute of the NIH by Cogan [96, 98, 99]. Symptoms of IK developed abruptly and gradually resolved, associated with photophobia, lacrimation, and eye pain which was unilateral or bilateral. Such symptoms tended to recur periodically for years before becoming quiescent. Vestibuloauditory dysfunction was manifested by sudden onset of Menière-like attacks of nausea, vomiting, tinnitus, vertigo, and frequently progressive hearing loss that characteristically occurred before or after the onset of IK. However within one to six months of the onset of eye symptoms, auditory symptoms progressed to deafness over a period of one to three months, certainly no longer than two years. With less than 100 reported patients with this rare childhood and young adult disorder, the majority of reported patients with typical Cogan syndrome have appeared as single case reports or patient series, often without pathological confirmation or evidence of systemic vasculitis in a biopsy or at postmortem examination. Early recognition of the diagnosis of childhood Cogan syndrome is

important in instituting corticosteroid therapy to preserve hearing especially when hearing loss is a later occurrence. A combination of oral and intravenous corticosteroids may be considered in children who partly but not fully improve. Most patients with Cogan syndrome (58%) treated with corticosteroids derived a favorable response in both vestibuloauditory and ophthalmologic manifestations, with the remainder demonstrating only ophthalmologic (23%) or vestibuloauditory improvement (19%) alone [100]. Other therapies include methotrexate (23%), cyclophosphamide (10%), azathioprine (5%), entanercept (3%), hydroxchloroquine (2%), and IVIg (2%). Surgical cochlear implantation can lead to objective and subjective benefits with improved hearing.

RECOGNITION OF SECONDARY VASCULITIDES

Cryoglobulinemic Vasculitis

The presence in the serum of one or more immunoglobulins (Ig) that precipitate below core body temperatures and redissolve on rewarming is termed cryoglobulinemia [100, 101]. Wintrobue and Buell [102] described the first patient with cryoglobulinemia, that of a 56-year-old woman who presented with progressive frontal headache, left face and eye pain; and right shoulder, neck and lumbar discomfort after a bout of shingles. This was followed by Raynaud symptoms, recurrent nosebleeds, exertional dyspnea and palpitation, and changes in the eye ground attributed to central vein thrombosis. Postmortem examination showed infiltrating myeloma of the humerus and lumbar vertebra, and splenic enlargement. A unique plasma protein was detected that spontaneously precipitated with cold temperature and solubilized at high temperature that differed from Bence-Jones proteinuria of other myeloma patients. Brouet and coworkers [103] provided modern classifications of cryoglobulinemia among 86 patients that included type 1, composed of a single monoclonal Ig; and types II and III as mixed cryoglobulinemia (MC), composed of different Ig, with a monoclonal component in type II, and polyclonal Ig in type III. In the absence of well-defined disease the presence of MC was termed “essential”. Since recognition of hepatitis C virus (HCV) infection in patients with MC [104, 105], and the recognition of the high rate of false-negative serological tests in type II MC [106], it became evident that HCV was associated in most patients with MC. Cryoglobulinemic vasculitis is characterized by the classical triad of purpura, weakness and arthralgia, frequent multiple organ involvement, and infrequent late lymphatic and hepatic malignancies. The commonest clinical manifestations of HCV- negative MC vasculitis in the CryoVas survey [107] included purpura (75%), peripheral neuropathy (52%), arthralgia or arthritis (44%), glomerulonephritis (36%), cutaneous ulcers (16%), and cutaneous necrosis (14%). A connective tissue disease was diagnosed in 30% of patients, and B-cell non-Hodgkin lymphoma (B-NHL) was noted in 22% of patients, whereas MCV was considered essential in 48% of patients. There was a greater frequency of joint involvement (53% versus 40%), peripheral neuropathy (74% versus 52%), CNS involvement (9% versus 2%) in those with HCV-MC compared to those with HCV-negative MC [108], with an equal frequency of purpura (71% versus 75%) and renal involvement (34% versus 35%). Cacoub and colleagues [109] noted five high prevalent extrahepatic manifestations in chronic HCV infection including, arthralgia (23%), paresthesia (17%), myalgia (15%), pruritus (15%), and sicca

syndrome (11%), and a 40% prevalence of cryoglobulins. These findings suggest the possibility of an independent role of HCV infection in the clinicopathological manifestations of MC and MCV. Among 114 patients including 18 children and 96 adults with cryoglobulinemia between 2000 and 2012, children had more frequent prolonged fever (17% versus 3%), petechiae and purpura (27% versus 15%), arthralgia and arthritis (66% versus 16%), and cutaneous involvement (77% versus 50%, than adults [110]. Aggressive optimal therapy of HCV-related CV with PEGylated (PEG)-INF alpha to improve the pharmacologic properties, and ribavirin with a protease inhibitor in the instance of HCV genotype 1 infection, should be considered as induction therapy for CV and administered for forty-eight weeks for all HCV genotypes [108]. An induction phase of immunosuppression such as rituximab plus antivirals is recommended in patients with more severe HCV-related CV exemplified by worsening renal function, mononeuritis multiplex, extensive skin disease including ulcers and distal necrosis [111].

Terrier and colleagues [107] showed a greater therapeutic efficacy of rituximab and corticosteroids compared with corticosteroids alone and alkylating agents with corticosteroids in achieving complete clinical, renal, and immunologic responses and a prednisone dosage of < 10 mg per day at six months. However, this regimen was associated with severe infections, particularly when high doses of corticosteroids were employed.

Plasmapheresis combined with immunosuppression can be useful in fulminant HCV-related CV to engender an immediate effect but should be continued to avoid post-pheresis rebound worsening. Rituximab, fludarabine, and cyclophosphamide treatment is effective treatment for refractory CryoVas associated with lymphoma. One-year, 2-year, 5-year, 10-year survival rates of 91%, 89%, 79% and 65% respectively, have been reported in patients with CV [108] with fatalities related to serious infection and disease flares of CV.

Systemic Lupus Erythematosus

Although distinctly uncommon, two collagen-vascular disorders, SLE and RA can be associated with vasculitis of the nervous system. The early concepts of the collagen-vascular disorders introduced by Klemperer [112, 113] stemmed from the appreciation of fibrinoid necrosis using collagen staining in patients with SLE. As collagen swells and fragments, it dissolves to form a homogeneous hyaline and granular periodic acid-Schiff (PAS)-positive material. The latter fibrinoid material contains immunoglobulins, antigen-antibody complexes, complement, and fibrinogen. The organ-specific responses to this fibrinoid material, especially of the CNS, leads to recognizable clinical sequela due to vascular and parenchymal damage.

The ACR delineated criteria for the diagnosis of SLE [114]. The recognition of neuropsychiatric lupus (NPSLE) was noted in 6.4% of a cohort of 1,253 SLE patients defined by the ACR [115]. According to Tomic-Lucic and colleagues [116] those with late-onset SLE due to development of disease after age 50 year, had a frequency of NPSLE of 6.6% compared to 36.6% in early-onset disease despite less major organ involvement and more benign course. Once thought to be an important cause of CNS or cerebral lupus, true vasculitis was present in only 12% of postmortem examinations in the series of Johnson and colleagues [117], and in 26.7% of late-onset SLE patients compared to 16.6% of those with

early-onset SLE. A comparison of the cumulative incidence of clinical manifestations in the two latter groups showed that seizures were more common in early-onset patients compared to later-onset patients (6.6% versus 0%), similarly for multiple cerebrovascular attacks (23.3% versus 3.3%), cranial and peripheral neuropathy (6.6% versus 3.3%). Nonetheless, there was no mention of CNS vasculitis among 150 patients with SLE described by Estes and Christian [118], despite the finding of neurological complications in 30% of patients that included focal deficits, seizures, dementia, stupor, and coma. Devinsky and colleagues [119] noted a prevalence of 3.5% of psychiatric involvement that included organic affective, delusional and hallucinatory syndromes in a cohort of 50 patients with SLE, one-half of whom had CNS lesions. Feinglass and colleagues [120] noted neuropsychiatric manifestations at onset of SLE among 3% of 140 patients compared to 37% in the course of the illness; however headache was not specifically tabulated. Cerebral dysfunction in SLE can be caused by large vessel or small vessel involvement or both. In the series by Feinglass and colleagues [120] vasculitis was noted overall in 28% of patients, as well as in 46% of those with neuropsychiatric involvement compared to 17% of patient lacking neuropsychiatric involvement. Postmortem examination of the CNS in ten of nineteen fatalities showed two cases of multiple large and small infarcts, which in one of them, demonstrated inflammatory cells infiltrates in the walls of medium-sized vessels, and perivascular infiltrates around small arterioles. Although active CNS vasculitis was absent in the brain and spinal tissue of all fifty patients reported by Devinsky and colleagues [119], two had evidence of inactive healed CNS vasculitis so suggested by focal disruption of the elastic lamina and mild intimal proliferation of a single medium-sized artery, one of which had active systemic vasculitis of the PAN type, both of whom evidenced Libman-Sacks endocarditis and embolic brain infarcts. Focal angiitis of the CNS with cyst-like formation around affected blood vessels was noted at postmortem in the patient described by Mintz and Fraga [121] with typical SLE rash, cutaneous vasculitis, and active neuropsychiatric involvement. Trevor and colleagues [122] summarized the literature of large named cerebral vessel occlusions from 1958 to 1965 noting one patient with a middle cerebral artery (MCA) stenosis progressing to occlusion and three others with angiographic internal carotid artery (ICA) occlusions, adding three new patients and suggesting a relation of the occurrence to cerebral arteritis. Two women, one age 21 and the other age 42 years, presented with headache followed by focal neurological symptoms attributed respectively to lesions along the left MCA followed by right ICA occlusions, and a right MCA stenosis progressing to occlusion in four months. A third patient had a left ICA occlusion without mention of headache. Among the four literature patients, one had angiographic occlusion of the MCA, and three others had occlusion of the ICA.

Johnson and colleagues [117] attributed the vasculitic nature of this process histopathologically to cerebral vasculitis mediated by acute inflammation and necrosis. Younger and colleagues [123] reported large named cerebral vessel occlusion attributed to circulating anticardiolipin antibodies in a young man in whom a vasculitic mechanism was not evoked. A number of fluorescent antibody tests provide serological support of SLE. The antinuclear antibody (ANA) screen produces a homogenous pattern in the majority of patients, with antibodies to native double-stranded DNA (anti-dsDNA) and reactivity to the smith (Sm) and ribonucleoprotein (RNP) antigens, the combination of which constitutes the extractable nuclear antigen (ENA). Circulating IgG and IgM antibodies with an affinity for charged phospholipids, antiphospholipid antibodies (APA), some of which have procoagulant activity such as the lupus anticoagulant (LAC) and the generic anticardiolipin (aCL) antibody

assay using cardiolipin as the antigen probe for APA are all important determinants of prothrombotic events, especially in the CNS wherein there is a propensity for occlusive microangiopathy. Circulating SLE-related antibodies can impact the CNS by affecting both vascular mechanisms and brain tissue directly. Immune complex mediated vasculitis probably affecting small vessels is thought to account for much of the damage in CNS lupus in light of spite of the paucity of cerebral vasculitis evident in the form of inflammatory infiltrates in vessel walls at postmortem examination. In those with discrete vascular infarcts, there is a known association with the presence of circulating pathogenic antibodies which predisposes some individuals to a high risk of stroke due to both small and large vessel occlusion [123, 124]. Lupus cerebritis and meningoencephalitis are two neurological disturbances that can be associated with preceding headache. So noted in up to 75% of patients with SLE depending upon criteria [125], an etiopathogenesis related to antibody-mediated neuronal dysfunction is likely given the lack of correlation of symptoms of NPSLE and CNS lesions at postmortem examination, together with the transient nature of the disturbance. Patients with SLE are also predisposed to infectious episodes including those yet treated due to impaired B-cell function and humoral immunity, in addition to others receiving immunosuppressant medication rendered impaired in T-cell function and cell mediated immunity [125]. The treatment of CNS Lupus should be guided by the tempo of the presenting neurological features, duration of disease activity, results of serological studies, comorbid disorders, and the presence of true vasculitis, with most patients receiving corticosteroids and those with true vasculitis of the brain considered for concomitant immunosuppressant therapy. Despite less major organ involvement and decreased incidence of neurological complications overall, late-onset SLE has a poor prognosis because of the higher frequency of comorbid conditions, longer exposure to classical vascular risk factors, both the less likelihood of treatment with higher doses of corticosteroids and the concomitantly higher rate of complications to cyclophosphamide when administered [116].

Rheumatoid Arthritis Vasculitis

A joint working group from the ACR and the European League Against Rheumatism (EULAR) published the 2010 classification criteria for RA [126]. Extra-articular RA (ExRA) occurrence is associated with increased comorbidity and mortality [127]. Criteria for severe ExRA were proposed in 2004 [128]. Active RA with high disease activity is associated with increased risk of severe ExRA manifestations. Major cutaneous vasculitis and vasculitis involving other organs are two such ExRA occurrences.

The diagnosis of RAV has generally been ascertained according to the criteria of Scott and Bacon [129] according to the presence of one or more of the following: 1) mononeuritis multiplex; 2) peripheral gangrene; 3) biopsy evidence of acute necrotizing arteritis plus fever and weight loss; and 4) deep cutaneous ulcers or active ExRA disease if associated with typical digital infarcts or biopsy evidence of vasculitis. Watts and colleagues [130] reported an annual incidence of RAV of 11.6 per million inhabitants between 1988 and 1992 in the Norfolk area of the United Kingdom, and a rate of 3.6 per million between 1998 and 2002. Myasoedova and coworkers [131] reported a ten-year cumulative incidence of 50% of any ExRA, including cutaneous and other organ-specific RAV in a retrospective population-based

cohort study of 463 RA patients in Olmsted County, Minnesota from 1995 to 2007. The ten-year cumulative incidence of RAV, but not other ExRA, was significantly lower in the 1995-2007 cohort (0.6%) compared to the 1985 to 1994 cohort (3.6%). The markers of RA severity including RA positivity, erosion and joint destructive changes (21% among those in the 1985 to 1994 cohort, compared to 29% in 1995 to 2007), use of methotrexate, other disease-modifying anti-rheumatic drugs, and systemic corticosteroids were significantly associated with ExRA development between 1995 and 2007. Vollerstein and colleagues [132] studied 52 patients with RAV at the Mayo Clinic from 1974 to 1981, who developed clinical vasculitis evidenced by classic ischemic skin lesions, mononeuritis multiplex, or a positive tissue biopsy in comparison to population controls. The initial manifestation of vasculitis was seen in skin (26 patients), nerve (20 patients) or both (3 patients), and mononeuritis multiplex presented in one (2 patients), two (9 patients), three (5 patients) or four nerves (4 patients). More than 90% of tissue biopsy specimens revealed vascular necrosis and inflammation. At diagnosis, 80% of patients began therapy with aspirin and other non-steroidal anti-inflammatory drugs however three-fourths continued or began corticosteroid therapy. Sixteen of the original 52 patients eventually received cytotoxic immunosuppressive therapy. Compared to the general population, those with RAV had decreased survival that was immediately evident and continued for six years. Compared with a previously reported incidence cohort [133] and adjusted for referral bias, survival of RAV was not different from classic RA. The factors that predicted decreased survival in RAV in a univariate proportional-HR model included older age, failure to receive previous non-steroidal anti-inflammatory drugs, previous administration of cytotoxic immunosuppressive agents, a higher dose of corticosteroids at diagnosis, decision to continue or initiate corticosteroids, and abnormal urinary sediment. Ouyang and coworkers [134] estimated CNS involvement in RA to be extremely uncommon, and other authors [135, 136] found CNS vasculitis to be decidedly rare. Puéchal and colleagues [137] found vasculitic involvement of vasa nervorum of both small- and medium-sized arteries indistinguishable from PAN in 64% of patients, with a mortality ranging from 28 to 44% according to the length of follow-up. Epineurial and perineurial vasculitis was observed with the same frequency among those with primary sensory neuropathy as others with predominant motor involvement, respectively 67% versus 64%. A greater extent of the neuropathy and motor involvement tended to predict decreased survival, however mononeuritis multiplex was not associated with a poor five-year survival rate (57%) than was distal symmetrical sensory or sensorimotor neuropathy (55%). Scott and Bacon [129] reported that five patients (24%) died in the group receiving methylprednisolone and cyclophosphamide, postmortem examination in four of whom failed to demonstrate active vasculitis.

By comparison, seven patients (29%) died receiving other treatments, of which one so studied at postmortem examination showed active vasculitis. Three forms of vasculitis classically occur in RA affecting all calibers of blood vessels from dermal postcapillary venules to the aorta, usually in association with circulating IgM and IgG rheumatoid factor as measured by the latex fixation test, decreased complement levels, and a positive ANA. The first is a proliferative endarteritis of a few organs, notably the heart, skeletal muscle, and nerves characterized by inflammatory infiltration of all layers of small arteries and arterioles, with intimal proliferation, necrosis, and thrombosis. The second is fulminant vasculitis indistinguishable from PAN with less severe leukocytosis, myalgia, renal and gastrointestinal involvement, and bowel perforation. The third type takes the form of palpable purpura,

arthritis, cryoglobulinemia, and low complement levels. The literature contains references to RAV with involvement of the CNS at postmortem examination in only nine patients. Detailed postmortem findings evidencing CNS vasculitis has been reported in only nine patients [134-136, 138-142] with accompanying clinical neurological findings including, delirium, confusion, seizures, hemiparesis, Gerstman-like syndrome, blindness, and peripheral neuropathy. Postmortem examination has shown widespread systemic vasculitis, single major cerebral artery involvement, generalized PAN-like changes in the CNS, isolated CNS vasculitis affecting the temporal lobes and brainstem with diffuse infiltrative thickening of the pia arachnoid, rheumatoid nodular formation, and inflammatory cell infiltration of leptomeningeal vessels in subjacent brain tissue including the midbrain, medulla, and upper cervical cord; and chronic perivasculitis and transmural chronic inflammatory cell infiltration with severe fibrinoid necrosis of the media of small leptomeningeal vessels and cortical arterioles.

Despite development of new and potent drugs for RA, there are no available evidence-based recommendations for treatment of systemic rheumatoid vasculitis [143]. Complete remission of systemic rheumatoid vasculitis occurred in nearly three-fourths treated with rituximab, with a significant decrease in daily prednisone dosage and an acceptable toxicity profile, making it a suitable therapeutic option to induce remission but maintenance therapy was necessary. Bartels and Bridges [144] recommended prednisone therapy to initially decrease systemic inflammation with a dose dependent upon the degree of systemic inflammation and level of organ system involvement. The presence of CNS involvement mandated intravenous corticosteroid therapy and consideration of cytotoxic or biologic agents from among them methotrexate, azathioprine, cyclophosphamide, anti-TNF agents and rituximab. Bartolucci and colleagues [145] reported the successful induction of a prompt symptomatic response in ten patients with systemic vasculitis not responsive to conventional treatment, including two with RA and associated vasculitis. Puéchal and colleagues [146] demonstrated evidence of efficacy of adjunctive anti-TNF therapy and corticosteroids for treatment of active refractory systemic RAV with remission achieved in two-thirds of patients, and a significant decrease in prednisone dose, with a higher risk of infection in the most severely ill patients.

Bacterial Meningitis

The category of secondary vasculitides related to infection includes acute bacterial and mycobacterial meningitis, spirochete organisms notably neurosyphilis, LNB, and viral agents notably VZV, and HIV/AIDS.

The relationship between vascular and parenchymatous cerebral changes including vasculitis, and acute and chronic neurological symptoms and signs was studied extensively in 9 infants and 5 children by Adam and colleagues [147] with *Hemophilus (H.) influenzae* meningitis. Fever, stiff neck, and alteration of consciousness followed a respiratory infection, with subsequent enlargement of the head and separation of the fontanelles, followed later by lethargy, coma and death despite sulfadiazine antibiotics and antiserum in the earliest stages of meningitis lasting one to two weeks (7 patients), moderate stages of two to four weeks (4 patients) or late in the stage of meningitis of more than four weeks (three patients). Vascular

inflammation by neutrophilic cells so noted in five patients (36%) was typified by inflammation of meningeal veins (2 patients) or meningeal arteries (1 patient) among those with early stage meningitis involvement; with involvement of meningeal arteries in the moderate stage patient, and in subarachnoid arteries of the patient in late stage meningitis. Vascular inflammation was absent in nine patients (63%), four of whom manifested vascular endothelial hyperplasia of meningeal vessels, while the remaining five were reported to have no vascular alterations. Based upon the clinicopathological findings, the authors [147] proposed that from the earliest stages of meningitis, pathological changes could be found in small and medium sized subarachnoid arteries and veins comprised of neutrophilic cellular inflammation accompanied by endothelial cell swelling, multiplication and crowding of lumina, a reaction that ensued over 48 to 72 hours. This was followed by infiltration of adventitial connection by neutrophilic cells, and in the intima of arteries accompanied by lymphocytes forming a conspicuous layer. Foci of vascular necrosis occurred in some cases. Vascular inflammation of the adventitia of subarachnoid vessels was believed to be due to involvement of the arachnoid membrane which formed the adventitia of the subarachnoid vessels, thus in a sense, the vessel wall was affected from the very beginning by the inflammatory process arising within itself. Subintimal inflammation was believed to have an origin in the foci of necrosis with spread beneath the intima along the line of least resistance. Spinal and cranial nerves surrounded by purulent exudates from the beginning of the infectious process at the base of the brain, were infiltrated by inflammatory cells only after several days, and not very pronounced in comparison to meningeal and cortical vessels, with comparatively more lymphocytes. Among 34 other infants and children reported by Smith and Landing [148] with *H. influenzae* meningitis of 2 to 42 days, six postmortem studied patients showed involvement of arterial vessels and venous lesions in 10 cases, three of whom had cortical necrosis and concomitant arteritis, and five had phlebitis. However in only one patient, a 10-week-old infant who died the evening of admission was arteritis believed to be responsible for brain damage. In this subject, postmortem examination disclosed acute inflammation of the walls of several veins and small arteries in the polymorphonuclear meningeal exudate overlying the cortical surface and extending into the superficial cortex, with narrowing of the lumina by endothelial proliferation and fibrin thrombi, associated with extensive early cortical necrosis.

Tuberculosis

Although the different forms of bacterial purulent meningitis was possible only after development of modern bacteriologic methods and the introduction of the lumbar puncture as a diagnostic measure by Quinke in 1891, TB meningitis was the first type of meningitis to be described clinically as dropsy of the brain in 1768, and subsequently shown to be inflammatory when meningeal tubercles and visceral tubercles were found to be identical in 1830. The tuberculoma, once the commonest intracranial tumor, is now exceptionally rare. The chief neurological signs and symptoms of tuberculous meningitis reflecting meningeal irritation are neck stiffness and positive Kernig sign; and raised intracranial pressure notably headache and vomiting with mental changes, seizures, and focal neurological signs. According to Smith and Daniel [149], arteritis is the rule in the vicinity of tuberculous

lesions, wherein vessel walls are invaded by mononuclear cells, with the adventitia more heavily involved than the media. The subintimal and intimal regions form a layer of homogenous fibrinoid material that later involves the media, and the vessel lumen is reduced by inflammatory cell exudation beneath the fibrinoid material, the end results of which are reduction or complete obliteration of the lumen, proliferative endarteritis, and cerebral infarction. The vessels most heavily involved are those at the base of the brain and others in the Sylvian fissure.

Pathologically-proven TB-associated CNS vasculitis was described in five heterogeneous patients [149-151]. The first patient described by Smith and Daniel [149] was an 18-year-old girl with fever, confusion, right hemiplegia, back and neck pain for several days followed by incontinence, complete flaccid paraplegia, delirium dementia, generalized spasticity and death. Postmortem examination showed advanced tuberculous meningitis with dense basal adhesions, hydrocephalus, and obliteration of the spinal subarachnoid space by adhesions, hemorrhagic infarction, and widespread arteritis with acute fibrinoid necrosis, without tuberculomas. The second case was Patient 4 of Greitz [150], a 4-year-old girl with fever, left arm weakness and increasing disorientation that rapidly progressed to coma, nuchal rigidity, and spasticity of the legs. Vertebral angiography showed local widening of a branch of the left posterior cerebral artery and a posterior fossa mass. The patient died soon afterward and at postmortem examination there was tuberculous meningitis with typical tuberculous vasculitis consisting of inflammatory changes in arteries at the base of the brain, notably in small vessels with intimal swelling leading to concentric narrowing of vessel lumina. Headache was a presenting symptom in one of three patients described by Leher [151], none of whom had a prior history of tuberculosis, and all of whom had diagnostic angiographic abnormalities and histopathologic evidence of tuberculous arteritis. A third pathologically-proven case of TB-associated CNS vasculitis was Patient 1 of Leher [151], a 33-year-old man with anorexia and insomnia. Carotid angiography showed narrowing of the supraclinoid ICA as well as narrowing of two convexity vessels in the Sylvian fissure. At postmortem examination there was marked eccentric left fronto-parietal region arterial narrowing due to fibroblastic proliferation of the intima with large numbers of inflammatory cells below the elastica. Headache was not mentioned in two other histopathologically confirmed patients with tuberculous vasculitis. The fourth case was Patient 2 of Leher [151], a 33-year-old man presented with fever and stiff neck. Cerebral angiography demonstrated irregularity of the supraclinoid ICA and reduction in the caliber of the convexity MCA vessels. He died shortly thereafter and postmortem examination disclosed tuberculous leptomenigitis and arteritis of the ICA and MCA with thickened vessel walls and narrowed lumina. The fifth case was Patient 4 of Leher [151], a 39-year-old man who presented with confusion and stupor, was found to have indentation of the lateral aspect of the ICA as it entered the subarachnoid space above the anterior clinoid on cerebral angiography. Ventriculography showed a block at the aqueduct of Sylvius. He died shortly thereafter and postmortem examination showed widely distributed systemic tuberculosis with binding of vessels at the base of the brain that showed arteritis, accompanied by infarction of the basal ganglia and brainstem.

Kopsachilis and colleagues [152] described a 39-year-old man without known tuberculosis, who developed sudden visual loss in one eye. Fluorescein angiography showed an infero-temporal branch retinal vein occlusion consisting of blockage with areas of hemorrhage, exudation, and late leakage. This was followed by optic disc swelling and headache. Biopsy of an enlarged cervical and submandibular lymph node revealed caseating

epithelioid ant cells confirming tuberculosis. Treatment with antituberculous treatment leads to improved visual acuity.

Syphilis

Meningovascular syphilis comprises 39 to 61% of all symptomatic cases of neurosyphilis and tends to occur more frequently in patients with concurrently infected HIV/AIDS. It is characterized by obliterative endarteritis that affects blood vessels of the brain, spinal cord and leptomeninges precipitating substantial ischemic injury.

Often referred to as Heubner arteritis, it involves medium-sized to large arteries with lymphoplasmacytic intimal inflammation and fibrosis however there is a variant form termed Nissl-Alzheimer arteritis that characteristically affects small vessels and produces both adventitial and intimal thickening. Both types can lead to vascular thrombotic occlusions and cerebral infarction, with preferential involvement of the MCA.

The search for the cause of stroke in young adults should include meningovascular syphilis as a potential etiology. Sudden acute severe headache heralded onset of occlusion of bilateral vertebral and proximal basilar artery documented by MRA [153] in a 35-year-old African man. He responded to thrombectomy with restoration of blood flow but succumbed to fatal pontine and subarachnoid hemorrhages. Postmortem examination revealed reactive plasma reagin (RPR) and a positive Venereal Disease Research Laboratory (VDRL) test in CSF with CNS vasculitis characterized by mural thrombi along the vertebrobasilar arteries with well-defined lines of Zahn of alternating layers of fibrin, platelet and red blood cell aggregates, and inflammatory cell infiltration of the arterial walls particularly in the adventitia. Headache of two to three weeks in duration were the presenting features of two other patients with stroke syndromes [27] one of whom had narrowing of bilateral M1 segments of the MCA, reactive CSF VDRL positive *Treponema pallidum* hemagglutinin-assay and fluorescent treponemal antibody-absorption (FTA-Abs) staining in the CSF, similar to second patient who instead presented with a stroke in the territory of the posterior cerebral artery (PCA) without focal changes on cerebral angiography, neither of whom were studied pathologically for true vasculitis.

One patient with abrupt onset of confusion, aphasia, and hemiparesis had carotid angiography that documented normal named cerebral vessels except for smaller than average caliber, with an abnormal complement fixation test of the blood and CSF, positive colloidal gold curve test, and leptomeningeal biopsy that showed lymphocytic infiltration, focal fibrosis, and chronic perivasculitis consistent with meningovascular syphilis [154].

Neither headache nor confirmatory pathological evidence of CNS vasculitis was mentioned in a patient with basilar artery stenosis and serologically confirmed syphilis in the CSF presumed to be due to meningovascular syphilis [155] so suggested by a positive string sign of the mid-basilar artery at cerebral angiography.

Lyme Neuroborreliosis

The term Lyme neuroborreliosis was introduced by Veenendaal-Hilbers and colleagues [156] in 1988 to emphasize that CNS involvement due to *B. burgdorferi* infection, the causative agent of Lyme disease. Among 20 patients described in the literature with neurovascular clinical syndromes ascribed to CNS vasculitis in which detailed information was available including documentation of positive CSF Lyme serology, two patients [157, 158] who presented with headache were ultimately noted to have histopathologically confirmed vasculitis on brain biopsy. Patient 3 of Oksi and colleagues [157] was an 11-year-old boy with headache and hyperactivity syndrome who developed gait difficulty concomitantly with a stroke visualized on brain MRI. Subsequent craniotomy and biopsy of the area of enhancement disclosed lymphocytic vasculitis of small vessels without fibrinoid necrosis, and CSF *B. burgdorferi* serology was positive. Headache and the MRI improved with intravenous antimicrobial therapy. Patient 2 of Topakian and coworkers [158] presented with headache, fatigue, malaise, nausea and vomiting first considered migrainous then psychosomatic until subsequent MRI disclosed ischemic brain infarctions, MRA was compatible with diffuse vasculitis, and CSF showed lymphocytic pleocytosis with positive oligoclonal bands, and diagnostic CSF and serum *B. burgdorferi* serology. Brain biopsy showed vasculitis involving leptomeningeal arteries comprised of lymphoplasmacytic vessel wall infiltration with focal necrosis. Epithelioid cells were beaded in multiple granuloma-like formations in the leptomeninges. There was symptomatic improvement after a course of intravenous antimicrobial therapy. A third patient reported by Miklosy and colleagues [159], a 50-year-old man with leg spasticity and CSF pleocytosis for 15 months who progressed to hemiparesis and ventilatory support, was later found to have diagnostic *B. burgdorferi* serology in serum and CSF. Postmortem examination showed perivascular lymphocytic inflammation of leptomeningeal vessels, some of which displayed infiltration of the vessel walls, duplication of the elastic lamina, narrowing of lumina, and complete obstruction of some leptomeningeal vessels by organized thrombi. Seventeen other patients with presumed CNS vasculitis due to *B. burgdorferi* infection of the CNS were reported, so suggested by complaints of headache [27, 28, 156, 162-164], while unmentioned in the case report of eight others [165-168], none of whom had histologically-proven CNS vasculitis.

Varicella Zoster Virus Infection

VZV is the cause of childhood chickenpox and most children manifest only mild neurologic sequela. However, after it resolves, the virus becomes latent in neurons of cranial and spinal ganglia of nearly all individuals, and has the propensity to reactivate in elderly adults and immunocompromised individuals to produce shingles. An uncommon but serious complication of virus reactivation is ischemic and hemorrhagic stroke. VZV vasculopathy affects both immunocompetent and immunocompromised individuals typically presenting with headache and mental status changes with or without focal neurological deficits and a spectrum of vascular damage from vasculopathy to vasculitis with stroke [169, 170]. Both large and small vessels can be involved and MRI shows multifocal ischemic lesions,

commonly at gray-white matter junctions. The diagnosis of VZV can be missed when symptoms and signs occur months after zoster, or in the absence of a typical zoster rash.

Fourteen patients with VZV-related vasculopathy with detailed clinicopathologic data have been described in the literature. One patient presented with headache, fever, mental status change, focal neurological deficits, and focal narrowing of the ICA, anterior cerebral artery (ACA) and MCA, with CSF antibodies to VZV, but without a rash [171]. VZV DNA and VZV-specific antigen were found in three of five cerebral arteries examined with histologically-confirmed CNS vasculitis involving the circle of Willis. Patient 1 of Eidelberg and colleagues [172] who presented with headache and herpes zoster ophthalmicus (HZO) rash was deemed to have CNS vasculitis based upon complete occlusion of the MCA and so treated, however postmortem examination showed no evidence of vasculitis. Headache was not mentioned in five other patients despite histologically-proven widespread small vessel granulomatous angiitis associated with lymphoma in two patients [173] and basilar branch vessel involvement of granulomatous angiitis in another [174]. One patient with contralateral hemiplegia one month after HZO was found at postmortem examination to have endarteritis of unilateral ACA, MCA and PCA [175] with VZV DNA from the involved vessels. One patient with AIDS, unilateral weakness and garbled speech due to ischemic infarction in association with lumbosacral zoster rash, was found to have CNS vasculitis of vessels of the circle of Willis with VZV DNA without herpetic inclusions at postmortem examination. Finally, neither headache nor supporting histopathology was present in seven other patients with VZV-vasculopathy including five patients with HZO and contralateral hemiparesis [176], and two patients with HZO and contralateral delayed hemiparesis [177].

Nagel and colleagues [178] analyzed virus-infected cerebral and temporal arteries from three patients with VZV vasculopathy. Several characteristic were noted in all VZV-infected arteries so studied including, disrupted internal elastic lamina, hyperplastic intima composed of cells expressing α -smooth muscle actin and smooth muscle myosin heavy chain but not endothelial cells expressing CD31, and decreased medial smooth muscle cells. The location of VZV antigen, degree of neointimal thickening and disruption of the media were related to the duration of disease. The presence of VZV primarily in adventitia early in infection and later in the media and intima supported the hypothesis that after reactivation from ganglia, VZV spread transaxonally to the arterial adventitia followed by transmural spread of virus. Stroke in VZV vasculopathy appears to result from changes in arterial caliber and contractility produced in part by abnormal accumulation of smooth muscle cells and myofibroblasts in thickened neointimal and disruption of the media [178]. Nagel and colleagues [178] also studied the immune characteristics of virus-infected temporal artery three days after onset of ischemic optic neuropathy, and after ten months of protracted CNS disease in the MCA. In both early and later VZV vasculopathy, T-cells, activated macrophages, and rare B-cells were found in adventitia and intima, whereas neutrophils and VZV antigen were abundant along with a thickened intima associated with inflammatory cells in vasa vasorum. Viral antigen but not leukocytes were found in the media in late VZV vasculopathy [179].

HIV/AIDS

Early in the HIV/AIDS epidemic, it was clear that a significant proportion of infected persons were intravenous drug users. Their associated risk behavior exposed them to infection through sharing of contaminated needles thereby increasing the risk of spread of HIV and other blood borne infections. The two postulated periods in the neurobiology of HIV when autoimmune disease manifestations and cerebral vasculitis can occur are shortly after seroconversion and before the spread of productive infection, and after initiation of highly active antiretroviral therapy (HAART) in association with the immune reconstitution inflammatory syndrome (IRIS) [180]. The timing of early HIV invasion has been difficult to ascertain based on the presence of one or well-recognized clinicopathological HIV/AIDS syndromes including HIV encephalitis, HIV-associated dementia and AIDS-dementia complex [181-183], all of which are indicative of symptomatic infection. Headache associated with irritation and confusion was the presenting feature of a 42-year-old homosexual man without evidence of immunodeficiency who developed cerebral granulomatous angiitis in association with human-T-lymphotropic virus type II (HTLV-III). At postmortem examination there was evidence of fibrous intimal scarring and marked luminal narrowing of the ACA, MCA and PCA and their proximal branches, with mononuclear cell infiltration of the vessel walls and numerous multinucleated giant cells near the internal elastic lamina. Six presymptomatic HIV-seropositive drug abusers by Gray and colleagues [160] had non-necrotizing cerebral vasculitis at postmortem examination.

IDENTIFICATION OF SINGLE ORGAN VASCULITIDES

Primary Angiitis of the Central Nervous System

Adult and childhood isolated angiitis or vasculitis are prototypical primary vasculitic disorders restricted to the CNS. Childhood and adult isolated CNS angiitis (IACNS), primary angiitis of the CNS (PACNS), granulomatous angiitis of the brain (GAB) and GANS, and adult and childhood PACNS (cPACNS) are all equivalent terms for a prototypical primary vasculitic disorder restricted to the CNS [184-188]. The diagnosis of PACNS [184], like IACNS [185] originally relied upon classic angiographic (Figure 3) or histopathologic features of angiitis within the CNS in the absence of systemic vasculitis or another cause for the observed findings. The typical patient with PACNS presented with headache of gradual onset often accompanied by the signs and symptoms of dementia, while only later developing focal neurological symptoms and signs. The clinical course might be rapidly progressive over days to weeks, or at times insidiously over many months with seemingly prolonged periods of stabilization. Those with GAB or GANS [186] presented with headache, mental change, and elevated CSF protein content with or without pleocytosis. Hemiparesis, quadriparesis, and lethargy were associated with a poor prognosis and mandated the need for combined meningeal and brain biopsy to establish the diagnosis with certainty. Granulomatous giant cell and epithelioid cell infiltration in the walls of arteries of various caliber, from named cerebral vessels to small arteries and veins, were noted at postmortem examination.

Figure 3. Radiographic features of cerebral vasculitis. Ectasia and beading in the M1 segment and lack of flow in the A1 segment of the right anterior cerebral artery (arrow).

A recent retrospective cohort of PCNSV from the Mayo Clinic [187] and a multicenter prospective cohort of PACNS from the French Vasculitis Study Group, French NeuroVascular Society and the French Internal Medicine Society [189] have stratified cases of based upon clinical, neuro-radiographic and histopathologic laboratory features, offering additional insights into the management of CNS vasculitis.

Between 2004 and 2011, Salvarani and collaborators [187] enrolled 105 patients, of whom (64%) met inclusion criteria for the diagnosis of probable CNS vasculitis based upon cerebral angiography manifesting areas of smooth-wall segmental narrowing or dilatation, and occlusions that affected multiple cerebral arteries without the proximal vessel changes of atherosclerosis or other causes); and 58 patients (36%) who met the definite diagnosis based upon a CNS tissue biopsy showing transmural vascular inflammation involving leptomeningeal or parenchymal vessels. The latter histopathology was granulomatous in 35 (60.3 %), lymphocytic in 13 (22.4 %), and necrotizing alone in 10 (17.2 %). These histological patterns appeared to identify subsets of disease rather than different stages of the same process since no individual patient had histological evidence of more than one pattern. A favorable response to therapy including corticosteroids (prednisone) alone or in association with cyclophosphamide was observed in 85% of patients. Three patients treated with biological agents including rituximab (1 patient) and a tumor necrosis factor- α inhibitor (2 patients) for treatment of refractory disease, were also improved. Relapses were observed in 27% of patients, and 25% of patients had discontinued therapy by the time of the last follow-up visit. While response to treatment was not associated with any histological pattern of the biopsy specimen, treatment with corticosteroids alone was associated with more frequent relapses (OR, 2.90), while large named vessel involvement (OR 6.14) and cerebral infarcts at the time of diagnosis (OR, 3.32) were associated with a poor response to treatment. Among the patients diagnosed exclusively by angiography alone, relapses were more frequent when there was large-vessel involvement (30%) than only small-vessel changes (9%), with an

increased mortality rate due to fatal neurovascular problems caused by PCNSV. Subsets of patients with PCNSV showed equally interesting insights.

An associated poor prognosis of GANS was noted by Molloy and colleagues [190] who described granulomatous vasculitis changes in CNS tissue biopsies of 10 of 13 (77%) patients with amyloid-beta-related angiitis (ABRA). Salvarani and coworkers [191] noted granulomatous vasculitis in all 8 (100%) cerebral biopsies of patients with lymphoma and PCNSV, two of whom had concomitant cerebral amyloid angiopathy. Among 131 consecutive patients with PCNSV, 11 (8.4%) had a rapidly progressive course that was resistant to immunosuppressive therapy resulting in severe disability or death. Such patients had bilateral cortical and subcortical infarction on initial brain MRI and LVV on cerebral angiography with granulomatous and necrotizing vasculitis in brain tissue biopsies. All 11 patients failed to respond to aggressive immunosuppressive therapy, only one of whom survived with major fixed neurological deficits.

In 2018, De Boysson and colleagues [189] described the treatment and long-term outcomes of an observational cohort of 112 patients with PCNSV derived from three main networks: the French Vasculitis Study Group, French Neurovascular Society, and the French Internal Medicine Society. The three main criteria inclusion were (1) involvement of CNS vessels evidenced by biopsy or based on imaging (on digital subtraction angiography or MRA), showing intracranial arterial stenoses, occlusions, or fusiform dilations); (2) a complete workup performed, including infectious and immunologic serologies (HIV, hepatitis B virus, hepatitis C virus, syphilis, tuberculosis, antinuclear and ANCA, echocardiography and whole body imaging, to exclude other alternative conditions affecting CNS vessels; and (3) a >6 months follow-up (unless the patient died before 6 months of a biopsy-proven PCNSV) to prevent the inclusion of other vasculopathies, such as reversible cerebral vasoconstriction syndrome (RVCS) where vascular lesions reverse within the first months [192]. The rate of prolonged remission was defined by the absence of relapse at ≥ 12 months after diagnosis; as was the functional status at last follow-up in accordance with three main groups of treatments administered: CS (group 1); induction treatment with CS and an immunosuppressant, but no maintenance (group 2); and combined treatment with CS and an immunosuppressant for induction followed by maintenance therapy (group 3). Good functional status was defined as a modified Rankin Scale score ≤ 2 at the last follow-up.

Among the 112 patients reported by De Boysson and colleagues [189], 33 (29%) patients were included with a diagnostic CNS tissue biopsy, and 68 (61%) and 11 (10%) respectively had digital subtraction angiography or MR angiography consistent with PCNSV. Remission was achieved with the initial induction treatment in 106 (95%) of the 112 patients. Prolonged remission without relapse was observed in 70 (66%) patients after a mean of 57 months (range 12-198) of follow-up. A good functional status at last follow-up (i.e., modified Rankin Scale score ≤ 2) was observed in 63 (56%) patients. The overall mortality was 8%. More prolonged remissions ($P=0.003$) and a better functional status at the last follow-up ($P=0.0004$) were observed in group 3. In multivariate analysis, the use of maintenance therapy was associated with prolonged remission (OR, 4.32 [1.67-12.19]; $P=0.002$) and better functional status (OR, 8.09 [3.24-22.38]; $P<0.0001$). These findings suggest that maintenance therapy with an immunosuppressant combined with corticosteroids leads to the best long-term clinical and functional outcomes in patients with PCNSV after having achieved remission with either corticosteroids alone or in combination with another immunosuppressant. In that regards, cyclophosphamide in combination with corticosteroids for induction, and azathioprine for

maintenance were the two main immunosuppressants used in this registry. Whether other combinations or sequences can achieve better results remained to be ascertained.

The past decade has also revealed insights into childhood PACNS (cPACNS) [193], one of the many childhood inflammatory brain diseases that affect small and large vessels. So called angiographically-negative small-vessel cPACNS (SVcPACNS) is associated with persistent headache, cognitive decline, mood disorder, focal seizures and abnormal brain neuroimaging in children. Brain biopsy findings include inflammatory cell infiltrates in intramural arterioles, capillaries, or venules consisting predominantly of a mixture of lymphocytes and macrophages, with occasional plasma cells, polymorphonuclear cells, and eosinophils. Granulomatous inflammation and multinucleated giant cells are generally absent. Awaiting the results of The PedVas Initiative, a Canadian and United Kingdom collaborative study (ARChiVe Investigators Network within the PedVas Initiative [ARChiVe registry], BrainWorks, and DCVAS) of pediatric and adult cases of AAV (GPA) and PACNS (NIH identifier, NCT02006134), there is yet satisfactory prevalence and incidence data or evidence-based guidelines to treat cPACNS. The PedVas Initiative has been prospectively collecting clinical and biobank data in January 2013 of registered cases, within 12 months of study entry. The approach to diagnosis and management has been to first differentiate cPACNS and SVcPACNS respectively from angiography-positive, and angiography-negative, brain biopsy-positive mimickers. However, it has been difficult to reconcile the early outcome results of the PedVas Initiative employing corticosteroids, cyclophosphamide, methotrexate, or rituximab for remission-induction of childhood GPA [73] for the analogous therapy of cPACNS using similar protocols for AAV, due to the disappointing rate of remission status (42%) and visceral organ damage (63%) in its study cohort.

The aim of treatment in cPACNS has nonetheless been to rapidly control the underlying inflammatory response and stabilize the blood-brain barrier while protecting the brain from further insults. Methylprednisolone has been the first-line agent administered intravenously at a dose of 30 mg/kg/day to a maximum of 1 gram per day for 3 to 5 days followed by 1 to 2 mg/kg/day of oral CS to a maximum of 60 mg/day of prednisone. After stabilization, immunosuppressive treatment is directed at the likeliest inflammatory pathways involved in the primary vasculitic process. Induction therapy with corticosteroids and pulse cyclophosphamide followed by maintenance therapy with azathioprine or mycophenolate mofetil has been recommended in cPACNS. Children with SV-cPACNS were treated in an open-label study [194] with cyclophosphamide in doses of 500 to 750 mg/m² monthly infusions for six months, and followed with maintenance therapy of azathioprine of 1 mg/kg/day and a target dose of 2 to 3 mg/kg/day, and mycophenolate mofetil at titrated doses of 800 to 1200 mg/m²/day followed for up to 24 months employing pediatric stroke outcome measures (PSOM). Among 19 such patients, 13 completed 24 months of follow-up, of whom 9 had a good neurological outcome by PSOM scoring, 8 experienced disease flares, and 4 achieved remission of disease; and mycophenolate mofetil was more effective than azathioprine. One retrospective analysis [188] found that cyclophosphamide conferred little benefit over azathioprine in patients with GAB so treated and in fact, increased the risk for potentially fatal side effects.

Figure 4. Central nervous system vasculitis. (A) The media and adventitia of this small leptomeningeal artery have been almost completely replaced by multinucleated giant cells (arrowheads). There is intimal proliferation with obliteration of the vascular lumen, and a dense, perivascular, mononuclear inflammatory infiltrate can be seen (stain, hematoxylin and eosin; original magnification, $\times 250$).

(B) A somewhat larger leptomeningeal vessel shows necrosis of the media and internal elastic lamina with multinucleated giant cell formation (arrows), intimal proliferation (arrowhead), and lymphocytic infiltration of the adventitia and neighboring meninges (stain, hematoxylin and eosin; original magnification, $\times 250$).

The approach to the patient with presumed PACNS begins with exclusion of disorders that can mimic primary CNS vasculitis including RVCS. The evaluation is incomplete without sampling of the CSF which often demonstrates elevation of the protein content and lymphocytic pleocytosis [188]. Cerebral angiography, high-resolution MRA and CTA, all provide complementary information however a small vessel vasculitis may escape detection, making it necessary to contemplate combined brain and meningeal biopsy for tissue confirmation (Figure 4).

Idiopathic Aortitis-IgG4-Related Disorders

In 1972, an unusual form of inflammatory aortic disease or aortitis came to light in the surgical literature with far-reaching implications for concepts of autoimmunity. Walker and colleagues [193] noted that 10% of 217 patients presenting with abdominal aneurysms at Manchester Royal Infirmary between 1958 and 1969 for resection showed excessive thickening of aneurysm walls and perianeurysmal adhesions at operation. Subsequent histological examination of the walls of the aneurysms showed extensive active chronic inflammatory changes including plasma-cell infiltration.

The clinical features of patients with inflammatory aneurysms differed from those with atherosclerotic disease due to generally younger age by a decade, lower incidence of rupture, lack of claudication of intermittent the limbs and presence of peripheral pulses, less likelihood of unusual presenting features, elevated ESR, and lack of calcification on preoperative abdominal Rojo-Leyva and colleagues [196] noted idiopathic aortitis in 43% of 1,204 aortic specimens gathered over a period of 20 years. In 96% of the patients with idiopathic aortitis patients and aneurysm formation, aortitis was present only in the thoracic aorta. In 2001, Hamano and colleagues [197] noted a high concentrations of IgG4 associated with sclerosing pancreatitis characterized by obstructive jaundice, infrequent attacks of abdominal pain, irregular narrowing of the pancreatic duct, sonolucent swelling of the parenchyma, lymphoplasmacytic infiltration, fibrosis, and a favorable response to corticosteroid treatment. One year later, Hamano and coworkers [198] noted the association of sclerosing pancreatitis with raised concentrations of IgG4 among those with concomitant hydronephrosis that caused ureteral masses later diagnosed as retroperitoneal fibrosis (RPF).

Histologic examination of ureteral and pancreatic tissues revealed abundant tissue infiltration by IgG4-bearing plasma cells. In the same year, 2008, three important observations were made. First, Sakata and colleagues [199] concluded that inflammatory abdominal aortic aneurysm (IAAA) was related to IgG4 sclerosing disease. Second, Kasashima and colleagues [200] concluded that IAAA was an IgG-RD together with RPF. Third, Ito and colleagues [201] described a patient with IAAA, hydronephrosis caused by RPF and high levels of IgG4, in whom treatment with corticosteroids led to clinical improvement and reduction in IgG4 levels. Histological inspection of the aortic wall specimen showed lymphocytoplasmacytic infiltration. Immunohistochemical analysis of the tissue showed IgG4 positive plasma cells. The findings suggested that IAAA had an etiopathogenesis similar to autoimmune pancreatitis and that some cases of IAAA and RPF could be aortic and periaortic lesions of an IgG4-RD. One year later in 2009, Khosroshahi and colleagues [202] described thoracic aortitis due to IgG4-RD with marked elevation of the serum IgG4 levels with progression to autoimmune pancreatitis, and Stone and coworkers [203] described IgG4-related thoracic aortitis with a media-predominant pattern of aortic wall infiltration and marked elevation of serum IgG4 levels, unequivocally linking IgG4-RD with thoracic lymphoplasmacytic aortitis.

Color-Doppler sonography, MRI combined with MRA and CTA, which adequately visualize the aortic wall and lumen, combined with FDG PET to detect increased uptake by metabolically active cells including inflammatory cells infiltrating the vessel wall, are essential in the assessment of the extent and severity of the various forms of aortitis including

IgG4 types. The histopathologic analysis of biopsy specimens has been the cornerstone of the diagnosis of IgG4-RD.

A 2012 consensus statement on the pathology of IgG4-RD by Deshpande and colleagues [204] proposed a terminology scheme for the diagnosis of IgG4-RD based upon the morphological appearance and tissue IgG4+ plasma cell counts in biopsy tissue. Three histopathological features associated with IgG4-RD included a dense lymphoplasmacytic infiltrate, fibrosis arranged at least focally in a storiform pattern, and obliterative phlebitis in morphological specimens. The majority of cells were T-cell with scattered B-cells, and an essential component of plasma cells with occasional eosinophils and macrophages. The level IgG4 antibody, which represents less than 5% of the total IgG in healthy individuals is tightly regulated and has a unique structure and functional property. It undergoes half antibody exchange *in vivo* resulting in recombined antibodies composed of two different binding specificities. Their production is driven in part by Th2 cytokines that mediate allergic reactions and IgE production. It does not activate complement pathways and has reduced effector function relative to other IgG subtypes. It remains unclear as to whether IgG4 directly mediates the disease process or reflects a protective response induced by anti-inflammatory cytokines, making it simply a valuable biological marker of IgG4-RD.

A Japanese consensus management guideline [205] suggested the initiation of oral prednisolone for induction of remission at a dose of 0.6 mg per kilogram per day for 2 to 4 weeks, with tapering by 5 mg every 1 to 2 weeks based on clinical manifestations, biochemical blood tests, and repeated imaging, to a maintenance dose of 2.5 to 5 mg per day for up to 3 months. Re-administration of corticosteroids is advised for treating relapses. Treatment with azathioprine, mycophenolate mofetil and methotrexate can be used as corticosteroid sparing agents or as remission-maintenance drugs after corticosteroid-induced remissions. Patients with recurrent or refractory disease and B-cell depletion may be considered for rituximab [206].

Nonsystemic Peripheral Nerve Vasculitis

The vasculitic neuropathies are heterogeneous disorders that present in the setting of systemic vasculitis or in the absence thereof where necrotizing arteritis may remain clinically and pathologically restricted to the peripheral nerves as a SOV. The Peripheral Nerve Society [207] established guidelines for the classification, diagnosis, investigation, and treatment of NSVN. Pathologically-definite vasculitic neuropathy is defined by active or chronic peripheral nerve and muscle tissue lesions that show cellular invasion of the walls of blood vessels with accompanying acute vascular damage (fibrinoid necrosis, endothelial loss/disruption, internal lamina loss/fragmentation, smooth muscle media loss/fragmentation/separation, acute thrombosis, vascular/perivascular hemorrhage or leukocytoclasia) or chronic vascular damage (intimal hyperplasia, fibrosis of media, adventitial/periadventitial fibrosis or chronic thrombosis chronic thrombosis with recanalization), without evidence of another primary disease process that could mimic vasculitis pathologically such as lymphoma, lymphomatoid granulomatosis or amyloidosis.

Patients with NSVN lack symptoms, signs, or laboratory evidence of involvement of other organs (demonstrable by laboratory evidence of PR3-, MPO-ANA, mixed cyro-

globulins, SSA, SSB, Sm, RNP, Scl-70, centromere, dsDNA, CCP serology; ESR >100 mm per hour, or tissue biopsy evidence of vasculitis in another organ other than muscle; serologic, PCR or culture evidence of a specific infection associate with vasculitis), and no predisposing factors (other than diabetes) of a connective tissue disease, sarcoidosis, inflammatory bowel disease, active malignancy, HUV, cutaneous PAN, or exposure to drugs likely to cause vasculitis. Inflammation of microvessels less than 40 to 70 μ m in diameter without vascular damage are broadly referred to as MV.

The management of NPNV has remained uncertain because of the very concept presumes that the vasculitic disease process is widespread within the nerves and not present elsewhere in the body. This assumption has been called into question by four lines of evidence.

First, the definition of NPNV allows for the finding of vasculitic lesions in muscle tissue, [207] perhaps making the syndrome more appropriately termed peripheral nervous system vasculitis or “PNSV”. Moreover, the detection of vasculitis in cutaneous nerve and muscle tissue specimens has been incorporated into the FVSG database to establish the diagnosis of systemic vasculitis. Among 129 patients with PAN [208] who underwent nerve biopsy with (108 patients) or without (21 patients) peripheral neuropathy, vasculitic lesions were noted in cutaneous nerve tissue in 83% and 81% of patients respectively, compared to 68% and 60% of cases where muscle biopsy tissue was examined.

Second, the lack of long-term follow-up in most cases series ranging from 6 months to 22 years [209].

Third, the report of only two proposed cases, both with foci of vasculitis outside the PNS in a visceral organ [19] or the temporal artery [210]. Patient 1 in the series of pathologically confirmed cases of PAN by Kernohan and Woltman [19] was a 54-year-old man with five years of progressive generalized painful peripheral neuropathy that was so severe before death that he was partially paralyzed, and unable to speak or swallow. Postmortem examination showed PAN limited to the nerve trunks of the arms and legs. The brain, cranial nerves, and spinal cord were normal except for early acute changes without evidence of vasculitis. Examination of all other organs failed to reveal a single vascular lesion, except one small artery in the capsule of the prostate gland. Torvik and Berntzen [210] described a 76-year-old woman with diffuse fever, pain, and central scotoma of the eye that improved with corticosteroids. A biopsy of the temporal artery and pectoralis muscle disclosed necrotizing arteries of small arteries and arterioles in small adventitial vessels of the temporal artery without frank temporal arteritis. However, postmortem examination evidence of healed vasculitis in numerous small arteries and arterioles of muscle and nerve tissue measuring 50 to 200 microns in diameter without vasculitis in visceral organ or the CNS. .

Fourth, the inclusion of patients with diabetes according to the 2010 guidelines [210] may be introducing selection bias. Over the years, there has been increasing support for the contribution of autoimmune mechanism in the pathogenesis of diabetic neuropathy. Diabetes itself appears to be caused by autoimmune mechanisms directed at insulin-producing pancreatic beta cells, and a variety of autoantibodies have been detected in patients with type-1 diabetes (T1D) or insulin dependent (IDDM), including anti-islet cell cytoplasmic antibodies, present in up to 80% of newly diagnosed patients and glutamic acid decarboxylase (GAD) antibodies, also present in patients with autoimmune stiff person syndrome. Younger and colleagues [211] reported the clinicopathologic and immunohistochemical findings of sural nerve biopsy tissues in a cohort of 20 patients with heterogeneous forms of diabetic neuropathy. That series was continued to a total of 107 patients [212], of which 3 (3%)

showed MV, and 3 (3%) showed necrotizing arteritis. Although diabetes has not been considered a predisposing factor in PNV, the presence or absence of diabetes became a defining feature of patients with LSRPN [213, 214]. In the only postmortem case of LSRPN described by Younger [215], sural nerve biopsy showed mononuclear inflammatory cells surrounding a small epineurial artery with extension into the vascular wall, with reactive luminal connective tissue suggesting recanalization of a thrombus. An adjacent nerve fascicle showed marked loss of myelinated nerve fibers. The patient was treated for painful diabetic lumbosacral plexopathy (DLSRPN) and peripheral nerve vasculitis according to prevailing standards with 2 g/kg intravenous immunoglobulin for 5 days, followed by 750 mg of intravenous cyclophosphamide and 1,000 mg of methylprednisolone intravenously for 3 additional days. Acute tubular necrosis, increasing lethargy, unresponsiveness, and aspiration pneumonia supervened and the patient expired 4 weeks after admission. General autopsy showed no evidence of systemic or peripheral nerve vasculitis. The brain showed diffuse loss of neurons in all sampled cortical areas, including the cerebellum, consistent with anoxia secondary to cardiac arrest. Sections of extradural lumbar plexus, sciatic, and femoral nerve tissue showed perivascular epineurial inflammation with infiltration of adjacent endoneurium. This case exemplifies the restricted nature of LSRPN as an example of a true NSVN.

There have far more studies of living cohorts with NSPNV. Kissel and colleagues [216] reported that 4.5% of 350 consecutive nerve biopsies performed at a single institution evidenced peripheral neuropathy secondary to necrotizing angiopathy. Six patients manifested a distal symmetrical sensorimotor polyneuropathy, while ten had a mononeuritis multiplex presentation, eight of whom had overlapping involvement of peripheral nerves that obscured the picture of mononeuritis. In three-quarters (12 patients), a specific underlying collagen vascular disease was not diagnosed despite extensive clinical, radiologic, and serological evaluation. Said and colleagues [217] studied 100 patients with necrotizing arteritis in muscle or nerve biopsy tissue that occurred in the context of a connective tissue disorder in fifty-five patients and in association with a disorder unrelated to connective tissue pathology in thirteen others. The commonest complaints at presentation in this cohort were specific cutaneous manifestation of vasculitis, including livedo, cutaneous necrosis, and nodules in one-third. Thirty-two patients had neuropathy only and necrotizing arteritis, the most common complaints at of which were spontaneous pain of neurogenic or muscle origin (48%).

More recently, Collins and colleagues [218] described forty-eight patients with NSPNV, 85% of whom had extensive, overlapping involvement of multiple nerves. Peroneal nerve and peroneal muscle tissue biopsy was 58% diagnostically sensitive compared to 47% for sural nerve biopsy for the diagnosis of vasculitis. Combination therapy with corticosteroids and cytotoxic agents was more effective than corticosteroids monotherapy for inducing remission and improving disability, with trends toward reduced relapses and chronic pain. Overall, ten patients died (21%) over the period of 63 months follow-up, five (10%) of whom were related to the disease or treatment, including two patients who succumbed to pulmonary emboli as a result of limited mobility of the legs or myocardial infarction in another; and two patients, one of whom had fatal sepsis and another metastatic bladder cancer as a consequence of cyclophosphamide toxicity.

There are no ongoing observational cohort studies to guide the treatment of NPNV. Recommendations for the treatment of NSPNV [210] include prednisone monotherapy unless there is rapidly progressive neuropathy at the dose of 1 mg per kilogram per day, with tapering over one year to a low dose. Combination therapy employing cytotoxic drugs

including cyclophosphamide, methotrexate, and azathioprine may be employed with adjuvant plasma exchange or IVIg. However, IVIg showed efficacy in a multicenter RCT of the treatment of small-to-medium systemic vasculitis due to EGPA with persistent disease activity [219].

This suggests that IVIg may be appropriate, first-line therapeutic modality in NSPNV. Moreover, the benefit of IVIg may be achieved without the risk of potentially fatal cytotoxic side-effects. However there has not been a prospective RCT of IVIg in NSPNV. A variety of mechanisms have been thought to be responsible for the beneficial effects of IVIg in NSPNV and other systemic vasculitides including neutralization of autoantibodies, inhibition of complement pathways, alteration of Fc receptor expression, and alteration of cytokine profiles [220]. Careful monitoring should be performed to observe desired therapeutic responses and to avoid potentially serious drug side effects.

CONCLUSION

In no other disorder have there been so many triumphs as in the diagnosis and treatment of primary systemic vasculitis. Physicians in a variety of subspecialties including neurology, rheumatology, immunology/allergy, dermatology and clinical pathologist, all working side-by-side, aided by subspecialties of public health, epidemiology, genetics, and clinical trial specialists, have benefited the outlook for individual patients and population cohorts around the globe. Yet it starts with clinical acumen typically of the general practitioner. This chapter on clinical approach was written with such diverse backgrounds in mind, from generalist to subspecialist with the hope that it will bring the field up to date and to the present.

ABSTRACT

The epidemiology of the vasculitides has been extensively studied over the past the years, yet despite this, there remain a number of areas where there is a deficit of data. The first problem is that the vasculitides are generally rare conditions and this makes conducting accurate epidemiological studies difficult. The second is the lack for some conditions, as for example, the anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) of a reliable and validated classification system. Overall, the vasculitides are diseases of the age spectrum, with Kawasaki disease and IgA vasculitis being conditions of childhood, and giant cell arteritis occurring in those age 60 years or more. The AAV also occur more commonly with increased age. The occurrence of the vasculitides in different ancestries has been less well studied, primarily because there are many health care systems in which it is not possible to derive epidemiological data. Kawasaki disease is much more common in far Eastern populations than Europeans, while IgA vasculitis is more common in Asians. Giant cell arteritis occurs in those of northern European ancestry. The AAV have an overall uniform occurrence, but granulomatosis with polyangiitis is more common than microscopic polyangiitis in Europeans, whereas the reverse is true in the Far East. Improving classification systems and health care systems will hopefully mean that some of the gaps in our knowledge will be filled over the next few years.

Keywords: epidemiology, primary systemic vasculitis, vasculitides

INTRODUCTION

The epidemiology of systemic vasculitis has been increasingly well described over the past 30 years; however, there remain formidable challenges and gaps in our knowledge.

Obtaining accurate epidemiological data is important for several reasons. Knowledge of the occurrence and pattern of disease in a given population is important for planning health services; identification of patterns of occurrence such as epidemics or seasonality may provide clues to the causes of disease both infectious and environmental. Comparison of disease occurrence between populations also provides clues as causation and also possible permit exploration of genetic risk factors.

The challenges fundamentally relate to the difficulty of conducting high quality epidemiology research in rare diseases. Accurate epidemiology requires a discrete population from within a well-defined geographical boundary. Universal health care systems with registration of patients receiving inpatient or ambulatory care are ideal for this type of research, in many parts of the world such universal health care systems do not exist and it is therefore much more difficult if not impossible to obtain reliable data. To collect a sufficiently large number of patients for reliable data from a rare disease either takes a long time or requires a large population, both of which make it harder to conduct high quality epidemiology research. A further requirement is a reliable classification system. The American College of Rheumatology (ACR) (1990) system for the classification of vasculitis is widely used, but has several major deficiencies in particular the absence of microscopic polyangiitis (MPA) and the results of ANCA testing. New classification systems are being developed as part of the Diagnosis and Classification of Vasculitis (DCVAS) project and will be available within the next 2 to 3 years. With increasing interest in the occurrence of disease in different populations accurate determination of ancestry is important, populations have become multi-ethnic with genetic admixture occurring. Such studies can be conducted either in a single population of multi-ancestry or by direct comparison of population in geographically dispersed areas, for example in the United Kingdom (UK) versus Japan. When comparing populations from different ancestries, it is important to ensure that the age structure of the studied population is the same. This is especially important for vasculitis, in which several types show a marked age tropism, as with IgA vasculitis (IgAV) and Kawasaki disease (KD) and giant cell arteritis (GCA) at opposite ends of the age spectrum.

Two main approaches have been used in studying the epidemiology of the vasculitides. The first is active surveillance with development of a complete cohort from a well-defined geographical area often based around a single referral center, examples being Norwich in the UK, Skane in Sweden, and Olmsted County in the United States (US) (Watts et al. 2012; Mossberg et al. 2018; Chandran et al. 2015). The second is passive surveillance using administrative databases, for example the UK Clinical Research Practice Database (UKCPRD) (Pearce et al. 2017). The former method has the major advantage that it is often possible to examine the individual patient case records to confirm the diagnosis and formally classify the individual patient. Because of the difficulties of collecting a complete cohort, such studies tend to have relatively small denominator populations, and total numbers of patients. The use of administrative databases has the advantage of automatic data collection, large populations and hence large numbers of patients. The downside is that it is usually impossible or impracticable to confirm the diagnosis and classification of any individual.

Algorithms are being developed which have been validated to extract information from administrative databases. (Sreih et al. 2016).

More recently, large-scale genetic epidemiology data has been published for many of the vasculitides. Again, there are formidable challenges to these studies, not least being the large number of well-characterized patients required for genome-wide association studies (GWAS). High quality data is now available for the large vessel vasculitides, Kawasaki disease and the AAV. This chapter focuses on the descriptive epidemiology of the vasculitides.

LARGE VESSEL VASCULITIS

The two main types of large vessel vasculitis (LVV), Takayasu arteritis (TAK) and GCA, are clinically considered to be the ends of a spectrum (Grayson et al. 2012). Recent genetic data, however, suggests that the two conditions are distinct (Carmona et al. 2017). It is well known that GCA occurs in the older patient age > 50 years whereas Takayasu arteritis (TAK) occurs predominately in those age < 40 years. This has left patients presenting with a large vessel vasculitis in their 40s essentially unclassifiable, and it is unclear whether they have late onset TAK or early onset GCA.

Takayasu Arteritis

Takayasu arteritis occurs in those age <40 years and presents with large LVV involving the aorta and its branches. For the purpose of epidemiological studies, the case definition has generally followed the ACR 1990 criteria for the classification of TAK (Arend et al. 1990).

There remains relatively little epidemiological data on TAK. The available data is summarized in Figures 1 and 2. Takayasu arteritis was first described in Japan and there has long been a view that it occurs more frequently in non-European populations. Most studies suggest there is a female predominance. In populations of European ancestry the annual incidence is 0.4 to 3.4/million, whilst it is 2.2/million in Kuwait/Arabia and 2.6/million in USA (Saritas et al. 2016; Dreyer et al.; Moriwaki et al. 1997). A recent Norwegian study observed an overall increase in the incidence over the last decade and a 3.5 to 5-fold difference in prevalence when comparing populations of north European ancestry to those of Asian and African ancestry respectively (Gudbrandsson et al. 2016). Although the incidence remains at similar levels in Japan, TAK is far more common in Japan with an estimated prevalence of 43/million with a strong female predominance (83.8%) and median age at onset at age 35 years, which was significantly lower in women (34 years) than males (43.5 years) ($P < 0.001$) (Watanabe et al. 2015).

Giant Cell Arteritis

Giant cell arteritis remains the commonest form of systemic vasculitis in those aged > 50 years. GCA is usually classified for epidemiology studies using the ACR 1990 criteria. Not all studies required a temporal artery biopsy to confirm the diagnosis, this can make it

difficult to compare studies. The incidence is highest in populations of northern European ancestry with the highest incidences and prevalence being recorded in Scandinavian populations, and in Olmsted County Minnesota, a population that is predominately of Scandinavian ancestry. The available data is presented in Figure 3. Some studies have suggested an increasing incidence but it is not always clear that this does not reflect better case identification and awareness of the disease. GCA is much less common in non-European populations especially from Asia. The prevalence in Japan appears to be 100-fold less than in Olmsted County. GCA is rarely observed in African ancestry populations (Kobayashi et al. 2003; Chandran et al. 2015). Some studies have suggested an increasing incidence over time, but it is not always clear that this does not reflect better case identification, changing rates of temporal artery biopsy and awareness of the disease. A recent Scandinavian study described a rise in reported incidence from 1972 to 1992 but no further increase up to 2012 (Brekke et al. 2017).

Figure 3. Annual incidence of giant cell arteritis.

Environmental factors have long been thought to be important in the etiopathogenesis of GCA. There is an inconsistent relation with season of onset, some studies reporting a summer time preponderance but this has not been confirmed. Infection has also been suspected but no clear link has emerged.

Genetic epidemiology studies have shown that HLA-DRB1*04 is the strongest risk factor for GCA, and it has been suggested that variation in population HLA-DRB1*04 frequency may partly explain variations in GCA incidence, with the incidence being higher in populations with the greatest frequency of HLA-DRB1*04 (Mackie et al. 2015).

In conclusion there is still no good explanation for the striking age tropism shown by GCA, immune senescence combined with a strong genetic background is the most likely explanation.

MEDIUM VESSEL VASCULITIS

Kawasaki Disease

Kawasaki disease is a medium sized vasculitis which predominately affects children age < 5 years, and is the predominant cause of childhood-acquired heart disease in the developed world (Burns & Glode 2004). It was originally described by Kawasaki in Japan in the 1960 but has been recognized as occurring in most populations, there are however, marked differences in occurrence between populations. Populations of Asian ancestry have the highest incidence of KD. The incidence of KD continues to increase in Japan in 2012, where the annual incidence rates were 243.1/100,000 population aged 0 to 4 years in 2011 and 264.8 in 2012/100,000 (Makino et al. 2015a). In Japan, the cumulative incidence now means that by

the age of 10 years 1.5/100 boys and 1.2/100 girls have been affected by KD (Nakamura et al. 2017). By contrast, recent data from Italy suggests that the incidence rate was 5.7/100,000 children 0 to 14 years old, and 14.7 years among children < 5 years (Cimaz et al. 2017). The present epidemiological data is summarized in Figure 4. Most studies suggest that it is more common in boys. In Japan, there have been several epidemics of KD but none since 1986, raising the possibility of an infectious etiology, however so far no single infectious agent has been identified.

Several countries have reported distinct seasonality in KD, but there is no overall pattern even allowing for differences in latitude and longitude. Japan reports two seasonal peaks of KD incidence in January and July, with a nadir in October (Makino et al. 2015a). Korea, at approximately similar latitude, has similar peaks in June/July and December/January. (Kim et al. 2017) Taiwan has peaks in May/June and the lowest incidence is reported from November to January (Huang et al. 2009). Seasonality data from China are more variable (Uehara & Belay 2012). In Chandigarh (India), a consistent peak in October with a nadir in February is observed. KD has been reported to occur more commonly in the winter months in mainland US, Canada and Europe, and in the more temperate regions of Australia.

In Europe, the USA and Australia, the previously observed increase in incidence appears to have plateaued. Whereas, in North-East Asian countries (so as Japan and Korea) (Makino et al. 2015b; Kim et al. 2014; Huang et al. 2009) report an incidence 10 to 20 times higher than the US and Europe, and the incidence is continuing to increase. The current incidence in Japan is 265/100 000 in those < 5 years of age (Makino et al. 2015a). China and India, the two most populous countries, from where only more recent and less complete epidemiological data are available, the incidence also appears to be increasing, mirroring rapid industrialization and economic growth.

Figure 4. Annual incidence of Kawasaki disease.

Polyarteritis Nodosa

Polyarteritis nodosa (PAN) is a rare vasculitis of medium vessels associated with development of aneurysms. Following the introduction of modern classification systems especially the 1994 Chapel Hill Consensus definition it has become increasingly uncommon (Jennette et al. 1994). It should be remembered that up until the 1990s the term PAN was used to cover several types of vasculitis, which would now be considered to be AAV. PAN is one of the few types of vasculitis for which a clear infectious cause has been recognized, Hepatitis B (HBV) infection is well-recognized cause of PAN. However, polyarteritis nodosa associated with HBV infection has become very uncommon since the introduction of vaccination programs and effective screening of blood donations. Before vaccination against HBV was available, more than one-third of adults with PAN were infected by HBV. Currently, less than 5% of patients with PAN are HBV positive.

The annual incidence of PAN currently ranges from 0 to 1.6 cases/million inhabitants in European countries. There is not a clear ethnic variation. There is a 1.5:1 male preponderance, and it occurs rarely in children (Figure 5).

SMALL VESSEL VASCULITIS

ANCA-Associated Vasculitis

The AAV (granulomatosis with polyangiitis [GPA], microscopic polyangiitis [MPA], eosinophilic granulomatosis with polyangiitis [EGPA]) have all been extensively studied over the past 20 years resulting in a large amount of available epidemiologic data. However, the field has been hindered by inadequate and poorly performing classification criteria, which has meant that it can be difficult to compare studies from different populations. Although widely used, the ACR (1990) criteria do not include MPA or ANCA testing, while the Chapel Hill Consensus Definitions from 1994 and 2012 were not intended to be used as classification criteria. These issues led to overlapping classification and inconsistency in their application. Results from the forthcoming DCVAS study may help to clarify this situation.

The overall incidence rates of AAV in Europe are reported to be in the range of 13 to 20/million (Figure 6), and the incidence of GPA has increased since the 1980s. The combined annual incidence of GPA and MPA in the UK was reported to be 1.5/million in the beginnings of the 1980s, and subsequently increased to 6.1/million at the end of the 1980s (Andrews et al. 1990). Similarly, during the same time period, the incidence of GPA increased in Sweden from 3 to 8/million (Knight et al. 2006). This increase could be due to several factors including: i) increased awareness among physicians, ii) the introduction of routine ANCA testing, and, iii) a genuine increase in incidence rates. However, the incidence has been stable since the early 2000s, suggesting that the likely explanation was increasing physician awareness following the introduction of routine ANCA testing. Geographical factors may also play a role. A comparison study from three regions in Europe showed overall incidence rates of all AAV to be quite similar; about 19/million (Watts et al. 2001). There were, however, differences in the incidence of GPA and MPA between northern and southern Europe; with GPA more common in the north, and MPA more common in southern Europe.

(Watts et al. 2001). However, the north-south gradient was not evident in southern Sweden which had an incidence rate of MPA more comparable to that of southern Europe (Mohammad et al. 2009). A recent Norwegian study reported higher rates of MPA than previously noted, suggesting that the north-south gradient might not be as pronounced as previously thought, or that there were changing environmental factors. Studies from New Zealand and Australia showed quite similar incidence rates for GPA comparable with those of northern Norway (Ormerod & Cook 2008; Gibson et al. 2006). By contrast, the proposed latitudinal gradient was observed in New Zealand (O'Donnell et al. 2007). Using the International Classification of Disease, patients coded as GPA were more frequent in southern New Zealand latitudes. Patients with EGPA were previously studied in the PAN group. The highest incidence rate for EGPA, 2.7/million (Watts et al. 2000) was reported from Norwich (UK); and recently 2.3/million (Ormerod & Cook 2008) from Australia.

The gender distribution of AAV is fairly similar in most studies with a slight increased ratio of men to women. The age-specific incidence for the whole group of AAV shows a clear increase with age. However, some variation has been reported between studies; the peak incidence in the age group of 55 to 64 years (Gonzalez-Gay et al. 2003), 65 to 74 years (Watts et al. 2000), and others $\geq$ age 75 years (Mohammad et al. 2009).

There is a need for studies in other regions and in other ancestries. There is only one study from central and Latin America as opposed to Europe and more recently Asia and Oceania. In a Peruvian population, MPA was more frequent than GPA (Sánchez Torres et al. 2005).

There are relatively few prevalence estimates compared with incidence studies of AAV. The prevalence of AAV is estimated to be 46 to 184/million (Ormerod & Cook 2008; Reinhold-Keller et al. 2000). The prevalence of AAV has generally increased over the last 20 years, reflecting improved patient survival and increased case identification, as shown by multiple retrieval sources.

Figure 5. Incidence of polyarteritis nodosa.

Source: Reproduced from Watts and Robson *Best Practice & Research Clinical Rheumatology* 2018, with permission.

Figure 6. Annual incidence of ANCA-associated vasculitis.

The prevalence of GPA doubled in northern Germany from 58/million in 1994, to 98/million in 2006 (Herlyn et al. 2014). A study from an urban multi-ethnic population of Paris showed a low prevalence of GPA of 23.7/million (Mahr et al. 2004). In Northern Europe, the prevalence of GPA in Norway increased from 30.4/million in 1988, to 95.1/million in 1998 (Koldingsnes & Nossent 2000), and was 160/million in Sweden in 2003 (A. J. Mohammad et al. 2007). The prevalence of GPA in the southern hemisphere was estimated at 112/million in New Zealand and 95/million in Australia (Ormerod & Cook 2008; Gibson et al. 2006).

There is a paucity of data on the prevalence of MPA which varies from 25.1/million to 94/million. (Figure 7). As expected, the prevalence of EGPA is much lower than either GPA or MPA, with the highest estimate being 45.7/million.

Genetic factors are clearly important as it has long been observed anecdotally that cases of AAV are relatively rare in non-Caucasian populations. The first study to show differences in the occurrence of AAV in different ethnic groups was reported from Paris, so suggesting that GPA was less common in people of non-European ancestry than MPA (Mahr et al. 2004). A study directly comparing two ethnically different populations, white UK Caucasian and the Japanese showed that the overall similar incidence rate for AAV, but GPA and PR3-ANCA vasculitis were much less common in Japan than in Europe (Fujimoto et al. 2011); whereas in Japan, MPA and MPO-vasculitis were the dominant form of AAV compared to Latin America (Peru) wherein MPA was more common than GPA (Sánchez Torres et al. 2005). In New Zealand, GPA was twice as common in Europeans than Maoris or Asians (O'Donnell et al. 2007). Large case series from China suggest that MPA is more common than GPA (Liu et al. 2008). A multi ethnic series from Chapel Hill, US found that GPA was relatively uncommon in African Americans (Cao et al. 2011). These differences may reflect global variation in the frequency of the allele HLA DPB1*0401, which has been associated

with GPA (Watts et al. 2014). The north-south gradient in Europe may also reflect genetic differences between northern and southern Europeans (Tian et al. 2009). The clinical phenotype of systemic lupus erythematosus (SLE) has been shown to differ between northern and southern Europeans (Chung et al. 2009) accounting for the different clinical phenotypes of AAV in northern and southern European populations commensurate with their different genetic background.

A recent study of the UKCPRD that investigated the role of preceding illness in the cause of GPA found a 5-fold (odd ratio [OR] 5.1 95% CI 2.7 - 9.4, $p < 0.0001$) increased risk of diagnosis of bronchiectasis in the 5 years preceding the diagnosis of GPA (Pearce et al. 2018). Patients with GPA were 2 to 3 times more likely than controls to have a previous diagnoses of an autoimmune disease and chronic renal impairment, and these effects also remained stable more than 5 years prior to diagnosis. People with GPA were more likely to have a diagnosis of pulmonary fibrosis (OR 5.7, 95% confidence interval [CI] 1.7 - 19.5, $p = 0.01$) and sinus infections (OR 2.7, 95% CI 1.8 - 4.2, $p < 0.0001$) recorded in the 3 years before diagnosis, but not before. A history of smoking, and a higher socio-economic status were significantly, but less strongly associated factors.

In an attempt to unravel the link between disease and latitudinal gradient, an ecological study was undertaken to examine the relationship between ambient ultra-violet radiation (UVR) and incident data from several international epidemiological studies. Ambient UVR was obtained from satellite data using the longitude and latitude of the largest urban center in any given area. The crude incidence rates of both EGPA and GPA increased with latitude, although only GPA achieved statistical significance. Using a negative binomial regression there was a modest increase in the incidence of both EGPA (3.4%) and GPA (3.5%) per higher degree of latitude. MPA showed no association in either analysis (Gatenby et al. 2009). Although UVR has local effects on the immune system in the skin (Ponsonby et al. 2005), and is of particular importance in SLE, the most plausible explanation for these findings is the effect on vitamin D synthesis, a hormone that has profound effects on the immune system, a finding observed in a wide range of inflammatory rheumatologic conditions. (Gatenby et al. 2013) There is however no population data on vitamin D from the cohorts for which we have AAV incident data and no series measuring vitamin D in patients and matched controls (Gatenby 2013).

Figure 7. Prevalence of ANCA-associated vasculitis.

Silica appears to be a consistently identified risk factor among existing case-control studies for both GPA and MPA. This is not surprising given its known association with a number of other autoimmune syndromes (Steenland 2005). Commonly inhaled, the association with AAV is observed even in the absence of respiratory tract disease so suggesting an impact beyond the immediately exposed airways. Environmental dust was likely proposed as an important determinant with an association to silica (Gómez-Puerta et al. 2013). Studies in Japan after two large earthquakes suggested an increased incidence in the years immediately after earthquake (Yashiro et al. 2000; Takeuchi et al. 2017). However, an increased incidence was not seen after the Twin Towers attack in New York (Webber et al. 2015).

IMMUNE COMPLEX SMALL VESSEL VASCULITIS

IgA Vasculitis

IgA vasculitis or Henoch-Schönlein purpura, is an immune complex vasculitis that predominantly affecting small vessels (Jennette et al. 2013). This common childhood systemic vasculitis has the clinical characteristics of cutaneous palpable purpura, arthralgia/arthritis, bowel angina, and hematuria/proteinuria. The annual incidence which ranges from 3.5 to 27.6/100,000 in children, is highest between the ages of 4 and 6 years (70/100,000) (Gardner-Medwin et al. 2002). Two recent European studies reported similar incidences; a suburban area of Paris described an annual incidence of 18.6/100 000 (13.6 - 24.5) children, and 17.5/100,000 (16 - 19.1) in Sweden (Piram et al. 2017; Mossberg et al. 2018). In the French study the annual distribution of diagnoses consistently showed a trough in summer months; 72% of children had infectious symptoms (mainly upper respiratory tract) a few days before the onset of IgAV; and 23% had a North African background (Piram et al. 2017). The outcome of IgAV in children is generally good with a low rate of development of renal failure.

IgA vasculitis is much less common in adults. Recent studies from Finland and Spain suggest an incidence of about 1.4 to 1.5/million adults, whereas earlier studies from the UK and Spain suggested an incidence up to 10-fold higher. It is not certain whether this represents different case capture approaches or classification. Adult onset IgAV is more common in males (63%) and has a mean age of onset of 50 years (Audemard-Verger et al. 2017).

Anti-Glomerular Basement Membrane Disease

Anti-glomerular basement membrane (GBM) disease or Goodpasture syndrome, is a vasculitis affecting glomerular capillaries, pulmonary capillaries, or both, with basement membrane deposition of anti-basement membrane autoantibodies. Lung involvement causes pulmonary hemorrhage, and renal involvement causes glomerulonephritis with necrosis and crescents. This autoimmune disorder presents mainly with rapidly progressive glomerulonephritis and pulmonary hemorrhage in conjunction with increased serum levels of anti-GBM antibodies. The target “Goodpasture antigen” is the non-collagenous (NC1) region

of the $\alpha 3$ chain of type IV collagen. Some patients also have ANCA present, leading to the suggestion of an overlap with AAV. Authorities debate whether the disorder represents a true vasculitis or a vasculopathy. An Irish study calculated the national incidence at 1.64/million per year during the 11-year period of 2003 to 2014) (Canney et al. 2016).

Cryoglobulinemic Vasculitis

Cryoglobulinemic vasculitis (CV) is a rare form of immune complex vasculitis in which circulating cryoglobulins are demonstrated in serum or tissue. There is an association with myeloproliferative disorders, connective tissue diseases, in particular hepatitis C virus (HCV) infection. The incidence and prevalence of CV vasculitis is unknown. The outcome is dependent on the underlying condition. Modern antiviral therapies for HCV are highly effective in curing the infection and consequently improving the prognosis of affected individuals.

Hypocomplementemic Urticarial Vasculitis

There is very little data on the epidemiology of hypocomplementemic urticarial vasculitis (HUVS). A study from Sweden reported on 16 patients (14 women) all of whom were anti-C1Q antibody positive during the years 2000 to 2015 and derived from a well-defined population of 1,474,105. The annual incidence was 0.7/million with a point prevalence on 31 December 2015 of 9.5/million. There was no detectable age variation. The median age of onset was 51 years. The 5-year survival was 92%, with a 10-year survival of 83% (Sjöwall et al. 2018).

OTHER VASCULITIDES

Behçet Disease

The epidemiology of Behçet disease (BD) is characterized by a striking geographic variation with a greater incidence in an area spanning from China to the eastern Mediterranean Sea, leading to the descriptive term, *Silk Road disease*. The majority of studies in BD have been prevalence rather than incidence studies including many from countries where the health care system is challenged to obtain accurate incidence figures. Two main methods have been used: census surveys and sample surveys.

A recent meta-analysis of 45 population based surveys confirmed the geospatial variation in the prevalence of BD (Maldini et al. 2018). The global overall prevalence was 10.3/100,000 inhabitants. In Turkey the pooled prevalence was 119.8/100,000 inhabitants, 31.8/100,000 in the Middle East, 4.5/100,000 for Asia and 3.3/100,000 for Europe (Maldini et al. 2018). In Europe, there was a north-south increase in prevalence, suggesting that BD in those of Northern European ancestry. The case finding methodology has also strongly influenced the reported figures, with sample surveys giving generally higher estimated of the

population prevalence compared census surveys; notwithstanding, the method employed to classify cases probably does not influence prevalence estimates (Maldini et al. 2017).

The geospatial distribution of BD is strongly related to expression levels of HLA-B*51, with prevalence being highest in Europe and the Middle and Far East, where HLA-B*51 is found in > 15% of individuals, and the prevalence being lowest in Africa (Wallace 2014).

SECONDARY VASCULITIS

Rheumatoid Vasculitis

Rheumatoid vasculitis (RV) first became widely recognized and reported in the 1960s. In the UK, the first estimate of the incidence was from Bath/Bristol in the 1970s and suggested an incidence of 6/million (Scott et al. 1981). In Spain, the annual incidence of biopsy proven RV during 1988–1997 was 6.4/million (González-Gay & García-Porrúa 1999). A detailed study conducted in Norfolk, UK, between 1988 and 2010, compared the incidence of RV between 1988 and 2000 with the period 2001 to 2010 (Ntatsaki et al. 2014). The annual incidence decreased from 9.1/million to 3.9/million. This decline occurred predominately during the late 1990s. The incidence in the Norfolk study was equal in both males and females. The decline in RV has been attributed to better disease control especially with the much wider use of methotrexate during the 1990s, and predates the common use of biologic drugs.

Several US studies have supported this decline in RV; a population based study of the incidence of extra-articular RA reported a reduction in the 10 year cumulative incidence of RV from 3.6% in 1985-1994 to 0.6% between 1995 and 2007 (Myasoedova et al. 2011). The reduction of the prevalence of RV was also reported in a serial cross-sectional study of both hospitalised and ambulatory patients from the US veteran population seen between 1985 and 2006, comprising a similar duration of cohort observation with our study of 22 years (Bartels et al. 2009). There has also been a decline in hospitalisation in California of SRV patients between 1980 and 2001 (Ward 2004).

CONCLUSION

The epidemiology of the vasculitides is much better understood now than was the case 20 - 30 years ago, however much of the data comes from populations of European descent. The main exceptions to this are KD and BD, which have very clear variations in geographical occurrence, for most other types of vasculitis it remains unclear how much geographical variation occurs. These variations give clues to possible genetic differences. There is still relatively little data from much of Asia especially the Indian subcontinent, Africa and Latin America. Knowledge of environmental risk factors is also sparse for most of the vasculitides.

ABSTRACT

Patient reported outcomes (PRO) using mainly the generic Short-Form 36 have been studied in diverse systemic vasculitides, in particular in patients with anti neutrophil cytoplasmic antibody-associated vasculitis (AAV), who report significant impairment in their health-related quality of life (HRQOL). Patients report different priorities regarding disease assessment compared with their physicians and this should be captured in clinical studies. The Outcome Measures in Rheumatology (OMERACT) Vasculitis Working Group, has gained endorsement by OMERACT for use of a disease-specific PRO, the AAV-PRO and generic Patient Reported Outcome Measurement Information System (PROMIS) instruments in clinical trials of vasculitis. Generic and disease-specific instruments are complimentary to each other and require further study to assess their utility in longitudinal settings, including their ability to distinguish between treatments of varying efficacy in randomized clinical trials (RCTs). This chapter reviews HRQOL measures in systemic vasculitis further separable by the caliber of vessels involved.

INTRODUCTION

Systemic vasculitis can be organ and life-threatening [1-3]. International randomized controlled trials with standardized outcome measurement have revolutionized their treatment [4-6]. Irreversible damage, ongoing disease activity and adverse effects of medications can all impact on Health-related quality of life (HRQoL) scores [7-9]. This chapter describes HRQoL and its measurement in systemic vasculitis.

CLASSIFICATION OF VASCULITIDES

The Revised 2012 International Chapel Hill Consensus Conference established distinct categories for the classification of vasculitis based upon the caliber vessels involved [10]. Large vessel vasculitis (LVV) including giant cell arteritis (GCA) and Takayasu arteritis (TAK) affects the aorta, its major branches and analogous veins. Medium vessel vasculitis (MVV) inclusive of polyarteritis nodosa (PAN) and Kawasaki disease (KD), involves main visceral arteries and veins and initial branches. Small vessel vasculitis (SVV) involvement affects intraparenchymal arteries, arterioles, capillaries, veins and venules, with disease mechanisms related to anti-neutrophil cytoplasmic antibody (ANCA) or immune complexes. The group of AAV includes granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA). The subgroup of variable vessel vasculitis (VVV) includes Behçet disease (BD).

BACKGROUND

Measurement of HRQoL scores in systemic vasculitis has historically been based on generic patient reported outcomes (PROs), mainly the Short-Form 36 (SF-36) [11]. The benefits of the SF-36 is that it is a well-recognized and validated outcome measure [11] and allows comparison between patients with systemic vasculitis and other conditions. Limitations in the use of generic PROs can include a reduction in face and content validity, as they have not been designed to capture areas of most interest to patients with that specific disease [12]. This lack of specificity reduces the ability to detect differences in state between patients and in the same patient over time [12]. In GCA, the SF-36 does not detect differences between patients with and without visual loss or systemic involvement for example [13]. Trials in AAV fail to show difference in SF-36 scores between arms, despite use of less toxic medications such as cyclophosphamide versus rituximab [14]. Whether this is a lack of sensitivity with the SF-36 or due to glucocorticoid effects in the arms remains unanswered. The difference in HRQoL scores as measured by the SF-36 in a randomized controlled trial (RCT) of tocilizumab in GCA, which may be attributable to the reduction in glucocorticoid-related adverse effects in the tocilizumab only arm [15], requires further analysis.

The Outcome Measurement in Rheumatology (OMERACT) initiative is an international collaboration to define core sets of outcome measurements for use in RCTs [16]. Working groups include researchers, clinicians, patient partners, and methodologists; other stakeholders including the Food and Drug Administration (FDA) and representatives from

pharmaceutical companies participate in the workshops [16]. The Vasculitis Working Group published a core set of domains and outcome measures for use in clinical trials in AAV in 2011 [17], and LVV in 2017 [18] and a core-set of domains for BD at OMERACT 2018. Due to the appreciation that patients and their physicians commonly rank aspects of their disease in different orders [19], groups have recently been focused on the patient perspective in systemic vasculitis. This has included the development of a new disease-specific PRO, the AAV-PRO [20], underpinning qualitative work in TAK and BD [21, 22] and evaluation of alternative generic PROs such as the Patient Reported Outcome Measurement Information System (PROMIS) [23].

Disease-specific PROs developed with patient involvement at every stage are in line with guidance from the FDA on the development of PROs [24]. They should be based on underpinning qualitative research with patients and the specific disease to identify the full range of impacts of the disease and its treatment, ensuring good face and content validity [25]. Themes rewritten as candidate questionnaire items, including stems and response categories, and corresponding questionnaire items are then piloted and tested within cognitive interviews to check readability and understanding [26]. Large scale testing within a survey is then performed, using statistical analyses such as Exploratory Factor analysis [27] and Rasch analysis [28] to confirm the ideal structure of the PROM and validate its measurement properties [20, 29].

Generic and disease-specific PROs are complimentary [30] and can be used together, and adapted to the specific context of the study. The growing recognition of the importance of PROs in the assessment of vasculitis, and the availability of validated instruments to capture PROs in vasculitis, will likely mean patients' perspectives will also be incorporated into composite outcome measures in future trials.

SMALL VESSEL VASCULITIS

ANCA-Associated Vasculitis

Vasculitic involvement in the subgroup of AAV variably effects the kidneys, lungs, nervous system, skin, ears nose and throat, and eyes, resulting in intrusive symptoms, and irreversible damage and impact on HRQoL [2, 31].

The generic SF-36 has been used in clinical studies of patients with AAV and is a core outcome measure listed within the 2010 OMERACT core set [17]. Data from four European RCTs of newly diagnosed patients with AAV demonstrated impairment in HRQoL at entry [32]. Physical functioning scores were the most affected, particularly in those with neurological involvement and of older age [33]. A Scottish case-control study demonstrated that patients with AAV were twice as likely to have fatigue than matched controls, with levels of fatigue strongly associated with impairment in physical function [34]. Survey data suggests that AAV-related fatigue is multifactorial, with associations seen with increasing levels of pain, sleep disturbance and inflammation [35]. Fatigue was ranked by patients as being of greatest importance to their HRQoL, in contrast to physicians, who ranked being dialysis or oxygen dependent as more important [19].

The OMERACT Vasculitis Group has identified the lack of a disease-specific PRO for AAV [36]. An international collaboration of researchers and patients has overseen the development of a new PRO to fulfill this unmet need. Qualitative interviews with 50 patients with AAV from the United Kingdom (UK), United States (US) and Canada identified the following domains of interest: symptom severity, and the impact of problems and limitations imposed by patients' ANCA-associated vasculitis and treatment on their work and domestic roles, family and social interactions, including activities and interests outside the home; and psychological state [31]. Themes used as underpinning data to develop candidate items for the new PRO and tested using cognitive interviewing and psychometric evaluation to create the final validated PRO [20].

The AAV-PRO 29-item questionnaire has six subscales/domains: "Organ-Specific Symptoms," "Systemic Symptoms," "Treatment Side Effects," "Social and Emotional Impact," "Concerns about the Future," and "Physical Function." The domains offer a comprehensive profile of the impact of AAV and its treatment on patients' everyday life [20].

AAV-PRO domain scores distinguish between patients who self-report active disease versus disease in remission, and therefore can be used as an outcome measure to define treatment success from the patient's perspective [20]. Scores for each separate domain are examined separately to provide a profile of the overall impact of the disease and its treatment on HRQoL. A greater focus is placed on pre-specified domains depending on the aims of the trial. For example, in a non-inferiority trial of a glucocorticoid-sparing agent, the treatment domain of the AAV-PRO might be key, but other investigators may instead wish to collect and analyze all domain scores to examine any differences across the symptoms and HRQoL domains. Further work is necessary to determine whether summary component scores are applicable to AAV-PRO.

Women scores are higher (i.e., worse) on all six subscales of the AAV-PRO [20] and in other conditions [37, 38]. Such trends in women were previously been reported in AAV [32]. Younger people (<65) scored higher (worse) on the Social and Emotional Impact subscale of the AAV-PRO, a trend also seen in other chronic diseases in this age group, potentially due to feeling different to peers, being unable to achieve ambitions and uncertainty at key stages of usual transition into adulthood [37, 39]. Younger age is a possible risk factor for negative illness perceptions in AAV, and increased levels of fatigue [40].

The PROMIS, which is a collection of generic item banks of self-reported health drawn originally from different diseases, in relation to fatigue and physical function, has been examined in patients with GCA, and appears feasible, with scores correlating with relevant SF-36 domain scores [23]. Further testing of different PROMIS item banks across other HRQoL domains within the systemic vasculitides is ongoing.

LARGE VESSEL VASCULITIS

Takayasu Arteritis

The symptoms of TAK are attributable to involvement of the aorta, its major branches, and the pulmonary arteries [41]. Constitutional symptoms related to systemic disease include

weight loss, fever and fatigue; while those associated with vascular inflammation and occlusion lead to pain, claudication and tissue loss [41].

Health-related quality of life examined in Turkish patients via generic SF-36 showed worse scores in patients with TAK than healthy controls, in line with scores from patients with ankylosing spondylitis and rheumatoid arthritis [42]. A patient survey in the US identified an association between use of immunosuppressant medications and worse HRQoL probably due to severity of disease, while younger patients and those in remission had better HRQoL [7]. Patients with TAK have higher levels of anxiety and depression than healthy controls as well as physical limitations [43].

A review by the OMERACT Large Vessel Vasculitis Working Group identified the lack of a disease-specific PRO for TAK [44]. Qualitative research, including individual interviews and focus groups in the US and Turkey have identified domains of importance to patients with TAK [21]. Salient themes include, “Pain and Discomfort,” “Fatigue and Low Energy Levels” and “Emotional Effects,” that could underpin the future development of a disease-specific PRO [21].

Giant Cell Arteritis

Giant cell arteritis is associated with inflammation of cranial and neck vessels [45] and is a medical emergency due to the risk of blindness in 20% [46, 47]. Prompt treatment with high dose glucocorticoids (GC) is needed to protect vision [48, 49]. Presenting features include vice-like headache, jaw claudication, flu-like symptoms and inflammatory pain and stiffness in the shoulders and hips (polymyalgia rheumatica, present in 50%) [47]. For 60 years GC alone have been the mainstay of treatment, but patients are concerned about the risks [50-53]. Patient report the psychological impact of weighing up the necessity of treatment with GCs to prevent blindness, versus fears about adverse effects [50]. The use of novel biologic medications such as tocilizumab versus standard GC regimens, does appear to benefit patients in terms of their HRQoL at one year [15], and this should be examined further.

Qualitative research in the UK has revealed the impact of GCA on patients' lives is due to their symptoms (e.g., pain, visual disturbance and musculoskeletal symptoms), adverse effects of glucocorticoids, and the disruption to normal life [54]. Patients fear blindness and have concerns about delay in diagnosis [54]. Patients with GCA ranked “losing sight in both eyes permanently,” “having intense or severe pain” and “feeling weak, tired or exhausted” as the most important domains of health-related quality of life [55].

The OMERACT Vasculitis Working Group has highlighted the development of a disease-specific PROM for GCA as one of the next steps in their research agenda [18, 56]. Generic PROs alone may not be specific enough for use in GCA. SF-36 scores in patients with GCA do not correlate with visual loss or systemic complications, so may be unable to differentiate between clinically important groups [13, 57].

Underpinning qualitative work with patients in the UK and Australia was presented, revealing themes including: “Anxieties around getting a diagnosis of GCA,” “Description of symptoms related to GCA and its treatment,” “Lack of bodily strength, stability and stamina; difficulties with completing daily tasks,” “Difficulties with participating in social activities, work and caring roles,” “Not feeling normal and impact on general perception of health,”

“Anxiety and fear of the future” [58]. Themes are being developed further into candidate questionnaire items for a disease specific PRO for GCA.

VARIABLE VESSEL VASCULITIS

Behçet Disease

Behçet disease is a variable vessel vasculitis affecting veins and arteries of different sizes [10]. Male and female patients present in young adulthood with a spectrum of different disease manifestations [59]. Organ involvement can include mucocutaneous (such as oral and genital ulcers, nodular and papulopustular skin lesions), ophthalmological (panuveitis), musculoskeletal (usually monoarthritis or arthralgia), neurological (from parenchymal stroke-like syndromes, to cerebral venous thrombosis [60]) and/or gastro-intestinal involvement (which can present in a similar to inflammatory bowel disease) [59].

Patients with BD have worse SF-36 scores compared with healthy controls, particularly in women and those with high disease activity [61]. Mucocutaneous (oral and genital ulcers), central nervous system, musculoskeletal and ocular involvement are all independent predictors of worse HRQoL [61]. Physical functioning is most impaired in panuveitis compared with other ocular presentations [61]. Sexual function can be impaired in men and women [62]. Patients reporting high activity in relation to their joints, oral ulcers and fatigue, scored highly on the physical domains of the Nottingham Health Profile (NHP); joint and oral ulcer activity was also correlated with high psychosocial subscale NHP scores [8].

A systematic review of outcome measures used in BD by the OMERACT Vasculitis Working Group revealed a lack of standardization and large variability in terms of outcomes used across trials [63].

There is a validated disease specific HRQoL measure, namely, the BD-QoL scale [29, 64-66] which has undergone cross-cultural adaptation and validation in Korean and Arabic [64, 67]. Item development was based on underpinning qualitative work with patients with BD in the UK, and included the following salient themes: “Relationships,” “Emotions,” “Limitations in Day to Day Activities” and “Self-Image” [29].

Generic measures to evaluate HRQoL in trials in BD have largely been the SF-36 [68] and the EQ-5D [63]. A range of different symptom-specific tools have been used, including the Oral Health and Related Quality of Life scale, which has been validated in Turkey and the UK in BD [69]. Symptoms specific tools to measure impact on Sexual Function (e.g., the Arizona Sexual Experience Scale [62] and Sleep (e.g., the Pittsburgh Sleep Quality Index [70]) have also been used, but not in a systematic way across trials [63]. Psychological impact has most commonly been measured within trials of BD using the Beck Depression Index [71] and Beck Anxiety Scale [66, 72].

The OMERACT Vasculitis Working Group continues to work towards standardized assessment of BD within clinical trials [22]. A new core set of outcome domains for BD, including HRQoL as a core domain, was ratified at OMERACT 2018. The core domain set will be published this year; next steps within the OMERACT process will be to evaluate and recommend appropriate tools with which to measure these domains, including HRQoL [73].

Use of generic, disease-specific and symptom specific tools may be appropriate depending on context, i.e., whether the trial is focused on a specific organ manifestation.

CONCLUSION

The impact of symptoms and side effects of treatment in systemic vasculitis can affect all aspects of HRQoL, depending on stage of life. Systemic vasculitis affects people of working age [74], those planning a family [75] or active retirement [54]. Patients also face the situation of having a rare autoimmune rheumatic disease [76] which can be isolating, results in delays to get a diagnosis and treatment, and difficulties in navigating health care systems between different specialists [76].

Key. SF-36: The Short Form 36; EQ5D: The EuroQOL five dimensions questionnaire; PROMIS: Patient Reported Outcome Measurement Information System; AAV-PRO: Disease specific PRO for ANCA-associated vasculitis; BD-QoL: Disease specific PRO for Behcet’s Disease; PSQI: Pittsburgh Sleep Quality Index.

Figure 1. Patient Reported Outcomes (PROs) in the Vasculitides.

Patients have different perspectives on their disease and its impact than their clinicians and it is important to capture this within clinical studies using validated outcome measures.

Chapter 196

NEUTROPHILIC CELL PATHOBIOLOGY IN THE VASCULITIDES

Akihiro Ishizu*, MD, PhD

Faculty of Health Sciences, Hokkaido University, Kitaku, Sapporo, Japan

ABSTRACT

Neutrophils play a critical role in the pathogenesis of vasculitides, especially in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). ANCA cooperates with pro-inflammatory cytokines in activating neutrophils. Activated neutrophils contribute to the development of small vessel vasculitis. The ANCA-cytokine sequence is pivotal to the understanding the pathogenesis of AAV. Recent studies reveal that neutrophil extracellular traps (NETs) extruded from activated neutrophils are implicated in vascular endothelial cell (VEC) injury. NETs are also implicated in the mechanism of ANCA production. These findings suggest that the NETs-ANCA vicious cycle is involved in the pathogenesis of AAV. This chapter updates the literature relating to ANCA-cytokine sequence theory.

Keywords: ANCA-associated vasculitis, ANCA-cytokine sequence, NETs-ANCA vicious cycle, NETs-ANCA-cytokine sequence

INTRODUCTION

Neutrophils play critical roles in the pathogenesis of vasculitides, especially in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). They are primed by pro-inflammatory cytokines, such as TNF- α , and express myeloperoxidase (MPO) and proteinase 3 (PR3) on the cell surface. ANCA binds to the antigen and simultaneously bridges the antigen and bystander Fc γ receptor on the cell, which activates neutrophils. Consequently, the activated neutrophil releases reactive oxygen species (ROS) and lytic enzymes, in turn

* Corresponding Author's Email: aishizu@med.hokudai.ac.jp.

contributing to the development of small vessel vasculitis (SVV). This ANCA-cytokine sequence therapy is pivotal for the understanding of AAV [1]. Recent studies have revealed that neutrophil extracellular traps (NETs) extruded from the activated neutrophils are also implicated in vascular endothelial cell (VEC) injury [2, 3]. Recent reports suggest involvement of NETs in the mechanism of ANCA production [4-6], as well as in ANCA-mediated cytotoxicity.

This chapter focuses on NETosis and the neutrophilic cell metamorphosis of NET formation in AAV.

Discovery of NETs

In 2004, Brinkmann and coworkers [7] reported that phorbol myristate acetate (PMA)-stimulated neutrophils extrude decondensed DNA that form extracellular web-like structure decorated with bactericidal proteins, such as MPO and PR3. These substances, termed NETs, bind to, and kill bacteria. NET formation is regarded as an important event of innate immunity.

Patients with chronic granulomatous diseases (CGD) who fail to generate NETs are susceptible to diverse bacterial and fungal infections. However, restoration of NET formation in CGD results in resistance to such infections [8]. NETs appear to be an innate response that binds microorganisms, prevents them from spreading, and ensures a high local concentration of antimicrobial activity derived from neutrophils [9].

Process of NET Formation

PMA-stimulated neutrophils undergo cell death with NET formation [10]. Since the characteristics of cell death resembles neither typical necrosis nor apoptosis, Steinberg and colleagues [11] coin NETosis for neutrophilic cell death with NET formation. NETosis induction by PMA requires activation of the Raf-MEK-ERK pathway, with NADPH oxidase-dependent production of ROS, and RIPK1-RIPK3-MLKL signaling [12, 13]. In this pathway, peptidylarginine deiminase 4 (PAD4)-dependent citrullination of histones induces decondensation of DNA resulting in a mixture of DNA and bactericidal proteins, contained originally in intracytoplasmic granules [14]. Thereafter, these substances extrude from the ruptured plasma membranes of neutrophils.

NETs in AAV

Kessenbrock and coworkers [4] first showed that ANCA derived from AAV induces NETs from TNF- α -primed neutrophils obtained from healthy donors. They also demonstrated co-localization of extracellular DNA, neutrophilic enzymes, and histones. NET formation was evident in crescents of glomeruli affected by AAV.

Subsequent investigations noted similar findings using citrullinated histones as a specific marker of NETs [15-17].

Vascular Endothelial Cell Toxicity of NETs

Carmona-Rivera and coinvestigators [18] demonstrated that direct incubation of VEC lines with NETs promoted VEC death. The cytotoxicity of NETs is mediated by matrix metalloproteinase (MMP)-9, which is externalized from neutrophils. NET formation and activation of MMP-2 in VECs culminates in cell death. The neutralization of MMP-9 prevents MMP-2 activation in VECs leading to a decrease in NET-mediated cytotoxicity.

Thrombosis Induced by NETs

Patients with AAV are predisposed to deep vein thrombosis (DVT), especially during the active stage of the disease [19]. As ANCA induces NET from the primed neutrophils, NETs are critically associated with DVT as histones within NETs bind platelets and coagulate blood [20, 21]. Such findings are consistent with an abundance of NETs detected in DVTs of patients with AAV [15, 17]. The collective findings suggest a link between AAV, accelerated thrombosis and DVT via NETs.

Degradation of NETs

NETs play an essential role in the innate immune system with excessive formation and persistence of NETs, a consequence of which is the heightened risk of adverse events. Notwithstanding, NETs are strictly regulated *in vivo*. The most important NET degradation factor is serum DNase I [22].

Propylthiouracil Induces DNase I-Resistant NETs

Propylthiouracil (PTU) is an anti-thyroid drug used for the treatment of hyperthyroidism. Approximately 30% of patients administered with PTU produce MPO-ANCA, some of whom develop MPO-AAV. The majority of PTU is metabolized in the liver. However, MPO in neutrophils also modifies PTU [23]. We hypothesize that PTU influences the formation or regulation of NETs and induces MPO-ANCA, and subsequently MPO-AAV [5]. We examined whether the addition of PTU created an impact on the formation or regulation of NETs *in vitro*. Widely extended DNA fibers studded with MPO are observed when human neutrophils are treated with PMA alone. To the contrary, treatment with PMA with PTU leads to a rounded-shape distribution of DNA fibers. The ensuing NETs surround dead neutrophils. Although DNase completely digests PMA-induced normal NETs, abnormal NETs induced by PMA with PTU is barely digested by DNase I. These findings clearly indicate that PTU influences NET formation and degradation by DNase I.

DNase I-Resistant NETs Cause ANCA Production

Next, we examined whether the DNase I-resistant NETs induced the production of MPO-ANCA *in vivo*. For this purpose, we generated rodent models. WKY rats and BALB/c mice are given oral PTU with intra-peritoneal injection of PMA [5, 24]. Contrary to the finding that widely extended NETs are observed in the peritoneal tissues of the PMA-injected models without PTU administration (PMA-treated models), NETs in the PMA-injected models with PTU administration (PTU/PMA-treated models) do not extend outward. Those in peritoneal tissues of PTU/PMA-treated models are significantly larger than NETs of PMA-treated models. These findings correspond to *in vitro* data indicating an abnormal conformation and impairment of NETs degradation induced by PMA with PTU. As expected, MPO-ANCA is produced in the PTU/PMA-treated models [5, 24]. Moreover, the amount of NETs in the peritoneal tissues and the titer of MPO-ANCA are significantly decreased when PTU/PMA-treated mice are administered the PAD inhibitor, Cl-amidine [24]. The collective findings clearly indicate that PTU induces the NETs disorder and the subsequent production of MPO-ANCA.

Implications of Disordered NETs in the Pathogenesis of AAV

Although most patients with MPO-AAV are not administered PTU, undetermined environmental factors that act like PTU, such as infectious exposures may induce the disorder of NETs and trigger the MPO-ANCA production resulting in the development of MPO-AAV [25].

NETs-ANCA Vicious Cycle in AAV

Hakkim and colleagues [22] demonstrated that a subgroup of systemic lupus erythematosus (SLE) patients hardly digested NETs because of the low activity of serum DNase I. Similar to SLE patients, serum DNase I activity in AAV is significantly lower than healthy controls [26]. These findings suggest that involvement of the NETs-ANCA vicious cycle in the pathogenesis of AAV (Figure 1).

Figure 1. NETs-ANCA vicious cycle in the pathogenesis of AAV. An excessive formation and/or persistence of NETs under low degradation condition can cause ANCA production. Simultaneously, ANCA can induce further NET formation from primed neutrophils.

The Formation of the Pauci-Immune Lesion in AAV

AAV is characterized by necrotizing crescentic glomerulonephritis and SVV. Although the pathogenic role of ANCA in the formation of necrotizing lesions can be demonstrated, there is little deposition of immunoglobulins (Ig) in affected tissues. This histological feature is termed, “pauci-immune”. Futamata and colleagues [27] reported the release of elastase from NET-forming neutrophils, digesting Ig, including ANCA, in pauci-immune lesions in AAV.

CONCLUSION

Neutrophils play a critical role in the pathogenesis of vasculitides, especially AAV. The ANCA-cytokine sequence is pivotal to the etiopathogenesis of AAV. There is an increasing literature supporting the role for an NETs-ANCA vicious cycle in AAV and the related contribution of NETs-ANCA-cytokine sequence theory.

ABSTRACT

Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are potentially life-threatening autoimmune diseases. The histopathological hallmark is a “pauci-immune” necrotizing crescentic glomerulonephritis. It has been assumed that the complement system is not involved in the development of AAV, however, new evidence suggests that the complement system is crucial in the pathogenesis of AAV. This article reviews updated information on clinical, *in vivo* and *in vitro* evidence for the role of complement activation in the development of AAV. Activation of the alternative pathway is crucial for the development of AAV, and the complement activation product C5a plays a central role. Activation of the alternative pathway of complement, at least in part *via* activated neutrophils, results in the generation of C5a, which is a strong chemoattractant for neutrophils. C5a is also effective in neutrophil priming, a process leading to increased membrane expression of the ANCA antigens, enabling neutrophils to be further activated by ANCA. Blocking complement, especially C5, is a potentially promising approach in the treatment of AAV.

Keywords: ANCA, complement, renal, vasculitides

INTRODUCTION

Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are life-threatening systemic autoimmune diseases, comprising granulomatosis with polyangiitis [GPA, previously named Wegener's granulomatosis (WG)], microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) [1]. ANCA are serological markers for the abovementioned vasculitides, predominantly IgG class autoantibodies against primary granule constituents of neutrophils and lysosomes of monocytes. By indirect immunofluorescence (IIF) on ethanol-fixed neutrophils, two fluorescence patterns of ANCA are distinguished, a cytoplasmic staining pattern (cANCA) and a perinuclear staining pattern (pANCA). Most patients with a cANCA pattern have ANCA directed against proteinase-3 (PR3) while pANCA is associated with several antigens, in particular, myeloperoxidase (MPO) [2].

Renal involvement occurs frequently in AAV and is histopathologically characterized by pauci-immune necrotizing crescentic glomerulonephritis (NCGN), characterized by little or no glomerular staining for immunoglobulins or complement. It was previously assumed that the complement system was not involved in the development of AAV, however, emerging evidence has suggests that activation of the complement system plays a significant role in the pathogenesis of AAV. This article reviews updated information on clinical, *in vivo* and *in vitro* evidence for the role of complement system in the development of AAV.

THE COMPLEMENT SYSTEM

At the turn of the nineteenth century, the complement system was already considered a major part of the innate immune system and is one of the main effector mechanisms of antibody-mediated immunity. A wide range of its biological activity is due to the cooperation of more than 30 plasma proteins [3, 4]. In humans, the complement can be activated *via* the three pathways: classical pathway, alternative pathway and lectin pathway.

The classical pathway is initialized when C1q binds to antibody attached to antigen, activating C1r and C1s, which cleave C4 and C2. The lectin pathway is activated when mannose-binding lectin (MBL) encounters conserved pathogenic carbohydrate motifs, activating the MBL-associated serine proteases (MASPs) and cleaving C4 and C2 the cleavage products of which form the classical and lectin pathway C3 convertase, including C4bC2a, which cleaves C3 into C3b and C3a. The latter is a chemo-attractant factor while sufficient C3b associates with C4bC2a to form the C5 convertase of the classical and lectin pathways, including C4bC2aC3b.

The alternative pathway is activated when C3 undergoes spontaneous hydrolysis and forms the initial alternative pathway C3 convertase, including C3(H₂O)Bb, in the presence of factors B and D, leading to additional C3 cleavage and eventual formation of both alternative pathway components C3 (C3bBb) and C5 convertase (C3bBbC3b). Properdin facilitates alternative pathway activation by stabilizing alternative pathway convertases.

All three pathways culminate in the formation of the convertases, which in turn generate the major effectors of the complement system that includes among others, anaphylatoxins C4a/C3a/C5a, membrane attack complex (MAC) and the opsonin C3b. Anaphylatoxins are

potent proinflammatory molecules derived from the cleavage of C4, C3, and C5. MAC is the terminal assembly of complement components C5b through C9, which directly lyse targeted surfaces. C3b induces phagocytosis of opsonized targets and also serves to amplify complement activation through the alternative pathway.

Due to the destructive potential of complement activation, especially in light of the potent feedback amplification ability of the alternative pathway, complement activities need to be confined to appropriate pathogenic surfaces. The generation of potent effectors needs to be tightly regulated to prevent collateral damage to healthy host tissues. Several steps are involved in complement activation checked by inhibitors so that the final system represents an intricate, homeostatic balance between the efficient detection and destruction of pathogens and the minimization of bystander tissue damage. Among them, complement factor H (CFH) is a key regulatory component of the alternative complement pathway. CFH impedes the formation of alternative pathway C3 convertases (C3bBb) by competing with factor B for binding to C3b, and accelerates the decay of C3bBb. CFH acts as a co-factor for the factor I-mediated proteolytic inactivation of C3b.

CD46, CD55 and CD59 are major membrane-associated regulators of complement in human cells. CD46 (membrane cofactor protein), is a ubiquitously expressed type 1 transmembrane glycoprotein that acts as a cofactor for factor I mediated cleavage of C3b and C4b, preventing formation of the classical and alternative C3 convertase. CD46 also regulates the amplification loop of the alternative pathway of activation of complement [5]. CD55 (decay accelerating factor) is a glycosylphosphatidylinositol (GPI) anchored protein, which serves to inhibit assembly of new C3 convertases and shorten the half-life of preformed convertases, thereby limiting their ability to participate in further complement activation [6]. CD59 (protectin) is a naturally occurring inhibitor of MAC found tethered to the membranes of cells via a GPI anchor [7].

Additional complement regulators include the above mentioned factor I, which mediates cleavage of C3b and C4b, preventing formation of active convertases; in addition to cofactor activity and surface-expressed complement receptor 1 (CR1). The latter exhibits decay accelerating activity and cofactor activity for factor I. C1 inhibitor, a serine protease that irreversibly binds to and inactivates C1r, C1s, MASP-1, and MASP-2, limits classical and lectin pathway activation, as well as C4-binding protein (C4BP) [8].

CROSS-TALK BETWEEN COMPLEMENT AND OTHER SYSTEMS

Cross-Talk between Complement and the Coagulation System

The complement and coagulation systems have a number of common characteristics and many potential implications for health and diseases. Activation of both systems lead to conversion of zymogens and assembly of proteolytic complexes that are mainly serine protease-mediated activation steps. Recent evidence indicates that some serine proteases, in particular, plasmin and thrombin from the coagulation cascade, directly activate C3 and C5, independent of the traditional C3/C5 convertase, generating biologically active C3a and C5a [9, 10].

The interaction between platelets and complement has important implications for innate immunity especially when the latter is in an activated form [11]. Platelets may express the receptors of C3a and C5a (C3aR and C5aR) [12], while C5b-9 may induce platelets to release α -granules and microparticles [13]. Del Conde and co-workers [14] found that activated platelets activate the complement system which in turn increases C3a generation, C3b deposition, and C5b-9 formation. For detailed information of the interaction between complement and platelets, see the comprehensive review by Speth and colleagues [15].

Cross-Talk between Complement and Pattern Recognition Receptors

Pattern recognition receptors (PRRs) are essential components in the innate immunity, recognizing pathogen-associated molecular patterns (PAMPs) and danger-associated molecular patterns (DAMPs) [16]. PRRs include Toll-like receptors (TLRs), leucine-rich repeat-containing receptors (NLRPs), nucleotide-binding oligomerization domain (NOD)-like receptors, RIG-I-like receptors, and C-type lectin receptors [17]. Examples of PAMPs include endotoxin or lipopolysaccharide (LPS) of gram-negative bacteria, lipoteichoic acid of gram-positive bacteria, and β -glucan of fungi [18]. The crosstalk starts when MBL binds to common carbohydrate PAMPs on gram-positive and gram-negative bacteria and yeast, as well as viruses and parasites, activating the lectin pathway through the abovementioned chain reaction [19].

Furthermore, substantial studies have revealed more intense interactions between complement and TLRs as well as NLRPs in a variety of inflammatory diseases. For example, Raby and co-workers [20] demonstrated *in vitro* activation of TLRs that mediated the down-regulation of C5a-like receptor 2 (C5L2), thus enhancing C5a-induced inflammatory responses. In a mouse model of polymicrobial sepsis, factor B, which is the unique component of the alternative pathway, acts as a downstream effector of TLR signaling [21].

Cross-Talk between Complement and Adaptive Immunity

The complement system provides a link between innate and adaptive immunity. Complement depletion can impair antibody production, as there might well be a requirement for functional C3 in the induction of thymus-dependent, but not thymus-independent antibody production [22]. The deeper mechanism might involve antigen-bound C3dg, and iC3b cleavage product binding to B-cell-expressed CR2 (CD21), which facilitates antigen presentation to B-cells, lowering the threshold for its activation [23].

There are other unexpected roles for complement as a regulator of T-cell immunity. Immune cells, including T-cells and antigen-presenting cells (APCs), produce alternative pathway complement components during cognate interactions [24]. The subsequent local complement activation yields production of the anaphylatoxins C3a and C5a, which bind to C3aR and C5aR respectively on both partners to augment effector T-cell proliferation and survival, while simultaneously inhibiting regulatory T-cell induction and function [25]. CFH, as an immunological brake, may directly affect the function of adaptive immunity by decreasing the production of key proinflammatory Th1-cytokines, including interleukin (IL)-

12, interferon (IFN)- γ , IL-6 and IL-8, from dendritic cells, while promoting the production of immunomodulatory mediators (IL-10 and transforming growth factor [TGF]- β), impairing effector CD4 (+) T cell alloproliferation and conversely, inducing Foxp3 (+) regulatory T-cells (Tregs) [26]. Figure 1 shows an overview of the complement system and the interactions with other systems.

Figure 1. The three pathways of complement activation: the classical, lectin and alternative pathways. There are three pathways of complement activation: the classical, lectin and alternative complement pathways. Activation of the classical pathway begins with the binding of immune complexes to C1q leads to the activation of its C1r and C1s serine protease subunits. Then, C1s activates C4 and C2 and subsequently results in the formation of the classical pathway C3 convertase, C4bC2a. The alternative pathway is initiated by hydrolysis of C3. Factor D cleaves the C3b-bound factor B, resulting in the formation of C3bBb, the C3 convertase. The lectin pathway is activated through the binding of MBL and MASP. MASP can cleave and activate C4 and C2 to form C4bC2a. Activation of any abovementioned pathway leads to activation of C3. Activation of C3 generates C3b and C3a, a chemo-attractant factor. Sufficient activation of C3 leads to the activation of C5. C5 activation leads to the formation of C5a and C5b-9. There are also crosstalk between the complement system and coagulation system, pattern recognition receptors and adaptive immunity.

PATHOGENIC ROLE OF ANCA AND NEUTROPHILS IN AAV

The pathogenesis of AAV is complex as can be appreciated in ANCA-mediated glomerulonephritis, which is attributed to possible infectious mediation and a multistep process that includes recruitment and priming of neutrophils to glomeruli. There, recruited ANCAs initiate injury by activation of primed and adherent neutrophils directly leading to

endothelial injury. ANCA-induced neutrophil activation also causes an inflammatory amplification loop leading to complement activation and generation of C5a that might in turn exert its role the development of AAV [27].

ANCA IN THE PATHOGENESIS OF AAV

The most convincing evidence for the pathogenic role of ANCA comes from animal studies. Xiao and co-workers [28] immunized MPO^{-/-} mice with mouse MPO and obtained MPO-ANCA IgGs or MPO-reacting splenocytes. MPO-ANCA IgGs or MPO-reacting splenocytes were injected into recipient mice. All the mice that received MPO-ANCA IgGs developed pauci-immune crescentic glomerulonephritis. The mice that received high doses of MPO-reacting splenocytes developed severe NCGN with systemic necrotizing vasculitis. Schreiber and co-workers [29] reported a modified mouse model of anti-MPO induced disease, further documenting the pathogenic potential of ANCA. MPO knockout (MPO^{-/-}) mice were immunized with mouse MPO and exposed to irradiation and transplanted bone marrow (BM) cells from either MPO^{-/-} or MPO^{+/+} wild type mice. Transfer of MPO^{+/+} BM cells into irradiated MPO^{-/-} mice led to disease development, while transfer of MPO^{-/-} BM cells into irradiated MPO^{+/+} mice did not, demonstrating that MPO^{+/+} BM-derived cells were pathogenic targets for anti-MPO IgG in the cause of disease. Little and co-workers [30] immunized rats with human MPO, inducing the generation of antibodies against human MPO, cross-reacting with rat neutrophils. Almost all the recipient rats developed pauci-immune glomerulonephritis and pulmonary capillaritis, indicating a direct pathogenic role of ANCA *in vivo*.

In vitro studies have verified the pathogenic role of ANCAs. Neutrophils stimulated by pro-inflammatory factors, especially TNF- α or C5a, target antigens of ANCAs, MPO and PR3, move from the cytoplasm to the cell membrane in a process termed priming. ANCAs combined with their target antigens, and cross-linked with Fc receptors on neutrophils, are induced to undergo a respiratory burst and degranulate, playing a direct pathogenic role in the development of systemic vasculitis [31]. A randomized controlled trial by the European Vasculitis Study Group (EUVAS) [32, 33] showed superiority of plasma exchange (PEX) over intravenous methylprednisolone in restoring renal function, thus supporting a pathogenic role for circulating ANCA in renal vasculitis.

NEUTROPHILS IN THE PATHOGENESIS OF AAV

Investigators [28] reported the development of NCGN in an experimental mouse model of accompanied by glomerular accumulation of neutrophils and macrophages providing direct evidence that neutrophils played a major role in the pathogenesis of anti-MPO-induced NCGN in this animal model and implicated neutrophils in the induction of human ANCA disease. Later studies [34] showed that neutrophil depletion prevented disease development in recipient mice. While pro-inflammatory mediators could prime neutrophils by inducing translocation of more ANCA antigens from the cytoplasm to the cell surface *in vitro*; ANCAs

further activate primed neutrophils to undergo respiratory burst and degranulation, suggesting the pathogenic role of neutrophils in AAV.

One other important mechanism of neutrophil effector function in the development of AAV was reported by Kessenbrock and colleagues [35] who found that ANCA-mediated neutrophil activation induced the formation of neutrophil extracellular traps (NETs), which are fibrous networks containing DNA, histones, and neutrophil granule proteins, triggering vasculitis and promoting the autoimmune response against neutrophil components. Excessive NETs formation was further found to be related to active clinical disease in patients with AAV [36]. NETs could enhance the uptake of ANCA antigens PR3 and MPO by myeloid dendritic cells [37], and activate autoreactive B-cells and ultimately the induction of ANCA [38].

EMERGING ROLE OF THE COMPLEMENT SYSTEM IN THE PATHOGENESIS OF AAV

ANCA-associated glomerulonephritis, characterized by pauci-immune NCGN histopathologically, showed little, if any, immunoglobulin and complement deposition in the glomeruli of AAV patients leading to the initial assumption that the complement system might not be involved in the development of AAV. However, observations in animal models and human disease, as well as increasingly sophisticated mechanism studies *in vitro* and in rodent models *in vivo*, have allowed a more nuanced understanding of complement system in the pathogenesis of AAV.

Evidence from the Animal Studies

Pre-treatment of mice with cobra venom factor to deplete complement, and C5 deficient mice fail to develop glomerulonephritis and vasculitis whereas disease development was comparable to wild type mice in C4-deficient mice, and C5- or factor B-deficient mice were completely protected from the disease [39]. This suggests that complement activation via the alternative pathway of complement system is critical to the development of AAV. The importance of inflammatory cell activation by C5a in amplifying the anti-MPO IgG-induced inflammatory response, was later appreciated. Huugen and colleagues [40] found that pretreatment with anti-C5 inhibiting monoclonal antibody prevented or strongly attenuated the development of ANCA-associated glomerulonephritis in mice. Schreiber and co-workers [41] investigated the role of the C5aR (CD88) in a model of ANCA-induced NCGN noting that C5aR-deficient mice were protected from developing NCGN. Xiao and investigators [42] further elucidated the role of C5a and its receptors in a mouse model of anti-MPO-induced NCGN, noting that CD88 deficiency ameliorated the disease, while C5L2 deficiency resulted in more severe disease. This indicated that CD88 enhances, while C5L2 suppresses, the inflammatory reactions. A recent study by Dick and co-workers [43] delineated the a role of CD88 in the generation of anti-MPO autoimmunity, and effector responses that resulted in renal injury by employing an experimental active autoimmunity to MPO by an anti-GBM

globulin trigger model, however the pathological changes were prevented by CD88 inhibition.

Evidence from Human Studies

Several studies found a certain degree of immune complex and complement C3c deposition, which correlated with poorer renal function [44, 45]. Chen and colleagues [46] analysed renal biopsies in 112 patients with ANCA-associated pauci-immune glomerulonephritis noting that C3c could be detected in glomeruli of a third of specimens. However, the intensity of C3c deposition was mild to moderate, and patients with C3c deposition had more severe lesions in the kidneys than those without C3c deposition, along with higher levels of proteinuria, poorer renal function at presentation, higher percentage of crescents and more severe tubulointerstitial lesions.

Scaglioni and co-workers [47] found that 26.4% of patients with ANCA-associated glomerulonephritis were actually not pauci-immune, and immune deposits were associated with higher proteinuria. Researchers investigated various components of complement in kidney specimens of patient. Xing and coinvestigators [48] found that C5b-9, C3d, and factor B, but not C4d, could be detected in the renal specimens; while C3d and factor B co-localized with C5b-9 in active glomerular lesions. The deposition of Bb, a marker of the alternative complement pathway activation in glomeruli of AAV patients correlated positively with the proportion of crescents, the extent of interstitial infiltrates, interstitial fibrosis and tubular atrophy; and negatively with the proportion of normal glomeruli [49]. Similar results were found in a study by Hilhorst and colleagues [50] who analyzed 187 renal biopsies of ANCA-associated pauci-immune glomerulonephritis detecting C3c, C3d, C4d and C5b-9 in the majority of tissue specimens. C3d and properdin staining were particularly associated with the proportion of cellular crescents, and presence of properdin correlated with the level of proteinuria. The staining of the two receptors of C5a, including CD88 and C5L2, were noted mainly on infiltrating neutrophils and macrophages in kidney specimens of patients with AAV. The staining of CD88 was down-regulated, while the staining of C5L2 was up-regulated, and that of CD88 was associated with initial renal function and the extent of interstitial fibrosis [51]. Given that CD88 can be rapidly internalized after the interaction with C5a [52], the down-regulation of CD88 in renal biopsies of AAV might be a result of C5a-mediated internalization and contribute to the self-protection mechanism to alleviate the C5a-mediated inflammation [51].

Besides the components of complement deposited in kidneys, Gou and co-workers [49] studied urinary levels of various components of complement in AAV patients noting that urinary levels of Bb, C3a, C5a and C5b-9 in active stage of AAV were higher than those in remission. In particular, correlation analysis showed that in patients with active AAV, urinary levels of Bb correlated with disease severity, including initial serum creatinine and the proportion of normal glomeruli in renal specimens. Circulating levels of various components of complement in AAV were also detected and similar circumstances were found in the circulation of AAV patients. Plasma levels of C3a, C5a, soluble C5b-9 and Bb were also elevated, while plasma levels of properdin were lower in active AAV compared to the remission phase. Plasma levels of C4d did not significantly differ between the active and

remission stages. Disease activity was related to plasma levels of Bb, the proportion of crescents in the renal specimen, erythrocyte sedimentation rate (ESR), and the Birmingham Vasculitis Activity Score (BVAS) [53].

Other studies [54-57] examined serum C3 and C4 levels in those with hypocomplementemia at diagnosis of AAV, noting a worse prognosis when present. A study by Manenti and colleagues [58] that included 46 patients with AAV, observing that 8 out of 30 renal biopsies had evidence of a thrombotic microangiopathy (TMA), similar to a large-Chinese cohort [59]. Manenti and colleagues [58] also noted that 35% of patients had a decreased C3 level in the circulation, and a low C3 level was associated with decreased renal survival and the presence of TMA.

Using proteomic analysis by mass spectrometry, Sethi and co-workers [60] found amounts of C3 and moderate amounts of C9, implicating activation of the alternate and terminal pathway of complement in pauci-immune NCGN with negative ANCA serology, suggesting that its cause may be promoted by a genetic or acquired defect in the alternative complement pathway.

CFH, which is a key regulator of the alternative complement pathway, inhibits amplification of the complement cascade both in the fluid phase and on host cell surfaces. Quantitative deficiency or impaired function of CFH, resulting in dysregulation of the alternative complement pathway, is involved in the pathogenesis of several autoimmune diseases, including TMA and C3 glomerulopathy [61-63]. Chen and colleagues [64] found that plasma CFH levels in active AAV patients were lower than those in remission, and related to parameters of disease activity, including BVAS, initial serum creatinine, and proportion of crescents in renal specimens. In multivariate survival analysis, plasma CFH levels were independently associated with the composite outcome of end stage renal disease (ESRD) and death. The functional activities of CFH including its interaction with, and the regulation of C3b; binding to mCRP and endothelial cells, and rendering of protection of host cells against complement attack, are all impaired in AAV patients [65].

Cheng and colleagues [66] reported that the expression levels of CD46, CD55 and CD59, the three major membrane associated regulators, were dysregulated in kidneys of patients with AAV, and associated with the severity of renal injury of AAV patients.

Evidence from *In vitro* Studies

Among the various components of the complement system, C5a plays a central role in the pathogenesis of AAV. Schreiber and co-workers [41] found that recombinant C5a dose-dependently primed neutrophils for an ANCA-induced respiratory burst. At the cellular level, activation of p38 mitogen-activated protein kinase (p38MAPK), extracellular signal-regulated kinase (ERK), phosphoinositol 3-kinase (PI3K) and protein kinase C (PKC) pathways were all indispensable steps in the translocation of ANCA antigens and activation of neutrophils by ANCA [67, 68].

Among the two receptors of C5a, CD88 contributes to the initiation of acute inflammatory responses, such as the respiratory burst and chemotaxis, while the function of C5L2 remains more controversial. C5L2 may function as a “default” or “scavenger” receptor, by competing with CD88 for binding of C5a [69, 70]; and a proinflammatory role for C5L2

has been suggested [71, 72]. By blocking C5L2 with neutralized antibodies, Hao and co-workers [73] found that C5a primed neutrophils could be mitigated, as well as the ANCA-induced C5a-primed neutrophils respiratory burst and degranulation, suggesting C5L2 might also play a pro-inflammatory role in C5a-primed neutrophils in ANCA-induced activation. However, that premise was inconsistent with the findings of Xiao and colleagues [42] who demonstrated that knockout of C5L2 was associated with more severe disease.

The reason for discrepancies in the function of C5L2 in AAV is not well understood but may be related to different *in vitro* and *in vivo* experimental environments, and differences in human and murine models of disease. Moreover, the function of C5L2 may be different in various cells, species, and disease contexts [74]. Whether C5L2 plays a pro- or anti-inflammatory role in the development of AAV will require further investigation.

Two key down-stream molecules, sphingosine-1-phosphate (S1P) and high mobility group box 1 (HMGB1), appear to play important roles in the cellular and molecular mechanisms of neutrophil activation by C5a. As a potent bioactive sphingolipid metabolite, S1P can regulate a number of cellular processes in autoimmune disorder [75-77], and participates in the regulation of the balance between expression of CD88 and C5L2 in endotoxin-induced lung inflammation [78]. According to Hao, and Sun and colleagues [79, 80] plasma levels of S1P are elevated in the active stage of AAV; and S1P is released from neutrophils in an autocrine or paracrine manner upon the C5a-priming process, which further activates neutrophils and injure glomerular endothelial. S1P may up-regulate the expression of CD88 on the surface of neutrophils, and blocking S1P receptors could attenuate activation of C5a-primed neutrophils by ANCAs and exert a protective effect in endothelial injury.

HMGB1 exists within the nucleus ubiquitously, but it becomes a pro-inflammatory mediator when released extracellularly [81]. Circulating and urinary levels of HMGB1 are associated with disease activity in AAV [82, 83], and HMGB1 could prime neutrophils by increasing translocation of the ANCA antigens PR3 and MPO. These primed neutrophils may be further activated by ANCAs, resulting in the respiratory burst and degranulation of neutrophils, and the formation of NETs [84, 85]. During the process of C5a priming, HMGB1 may be released from the neutrophil cytoplasm into the extracellular space, further enhancing the effects of C5a on neutrophil activation. Blocking HMGB1 could mitigate C5a-mediated translocation of ANCA antigens, and ANCA-induced respiratory burst and degranulation of C5a-primed neutrophils [86]. HMGB1 could exert its direct or indirect role on the endothelial injury in the presence of ANCAs [87, 88]. Hence the interactions between S1P and C5a, as well as HMGB1 and C5a, play a notable role in neutrophils for ANCA-mediated activation.

Complement activation could lead to the activation of neutrophils and further activate the complement system especially via the alternative pathway. In the study by Xiao and co-workers [39] supernatant from human neutrophils stimulated with ANCAs activated complement in normal human sera, a finding indicating that ANCA-activated neutrophils may release certain substances that subsequently activate the complement system. Camous and colleagues [89] demonstrated that activated neutrophils could further activate the alternative complement pathway via their cell membranes and microparticles.

Leffler and colleagues [90] discovered that NETs could activate the complement system via the classical pathway by the interaction with C1q. Wang and co-workers [91] noted that NETs released from ANCA-activated neutrophils could activate the complement system via the alternative pathway. Schreiber and colleagues [92] observed that NETs provided a scaffold for alternative pathway activation that in turn contributed to endothelial cells

damage. They further established the *in vivo* relevance of NETs and the requirement of RIPK1/3/MLKL-dependent necroptosis for disease induction using both murine AAV models and in human kidney biopsies.

An *in vitro* study by Chen and coinvestigators [93] revealed pathophysiological mechanisms of CFH in the pathogenesis of AAV. On one hand, CFH inhibited ANCA-induced neutrophil activation by interacting with neutrophils and protected against glomerular endothelial injury, indicating a deficient function of CFH from patients with active AAV in their ability to bind neutrophils and inhibit neutrophil activation by ANCAs. On the other hand, MPO, which could be released from ANCA-stimulated neutrophils, influenced the complement regulatory activity of CFH [94]. Those would contribute to better understanding of complement system in the pathogenesis of AAV.

EVIDENCE OF CROSS-TALK BETWEEN COMPLEMENT AND OTHER SYSTEMS IN AAV

Cross-Talk between Complement and Coagulation System in AAV

The complement and coagulation systems have a number of common characteristics and have many potential implications for health and diseases.

Several studies have reported that patients with AAV are in a hypercoagulable state, with an increased risk of developing venous thromboembolic events (VTEs) [95-97], indicating the involvement of coagulation system in AAV. C5a was found to induce expression of tissue factor (TF) on neutrophils and endothelial cells, thus triggering the extrinsic coagulation system [98, 99]. Huang and colleagues [100] found that stimulation of neutrophils with C5a and ANCAs not only resulted in the respiratory burst and degranulation, but also led to release of TF bearing microparticles and NETs; and subsequently activated the coagulation system and thrombin generation.

Platelet counts are usually elevated in patients with active AAV. Willeke and co-workers [101] found that platelet counts correlated with disease activity in AAV, while Miao and colleagues [102] demonstrated that platelets were activated in AAV via thrombin-PARs pathway, and could activate the alternative pathway of complement, further enlightening the connection between the complement system and platelets.

Cross-Talk between Complement and TLRs in AAV

In an animal model of MPO-AAV mediated by passive transfer of anti-MPO antibodies, LPS can aggravate the disease via a TLR4 dependent manner [103]. Wang and colleagues [104] investigated the renal expression of TLRs in kidneys of patients with AAV by immunohistochemistry noting that expression of TLR2 and TLR4 was up-regulated in AAV, while that of glomerular TLR4 was inversely related to baseline serum creatinine and the proportion of crescents. HMGB1 is a typical ligand of TLR2 and TLR4. The interaction of HMGB1 and C5a likely plays an important role in ANCA-induced neutrophil activation [86]

like that of both complement and TLRs in AAV. The role of PRRs other than TLRs have received little attention in AAV.

Cross-Talk between Complement and Adaptive Immunity in AAV

The study by Dick and colleagues [43] revealed the genetic absence or pharmacological inhibition of CD88 resulting in reduced autoimmunity to MPO, with an attenuated Th1 response, increased Tregs, and reduced generation of MPO-ANCA.

Figure 2. The roles of complement system in a proposed working model showing the pathogenic events of ANCA-associated vasculitis.

One other study using murine models of MPO-AAV by the same author [105] found that C3aR did not alter histological disease severity. However, it promoted macrophage recruitment to the inflamed glomerulus and inhibited the generation of MPO-ANCA while not influencing T cell autoimmunity. Thus, complement activation, especially via the alternative pathway, plays an important role in the pathogenesis of human AAV, indicating potent and promising intervention targets for management of patients with AAV and ameliorating the course of ANCA-mediated disorders. Figure 2 shows the pathogenic role of complement in the pathogenesis of AAV.

IMPLICATIONS FOR MANAGEMENT OF PATIENTS WITH AAV

As progress is made in understanding the molecular pathogenesis of this disease, new targets will be found for potential therapeutic attack, including targeting C5, C5a/C5aR, C1 and C3. Eculizumab, the first available anti-complement treatment, is a fully humanized recombinant monoclonal antibody that binds C5 with high affinity. Eculizumab efficiently blocks C5 cleavage and prevents the formation of C5a and C5b-9 [106]. Several well-

designed studies have demonstrated the therapeutic efficacy of eculizumab in paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic-uremic syndrome (aHUS) [107-109], leading to approval of eculizumab for these indications by the FDA. Subsequent small-scale studies and case reports have studied eculizumab in other renal diseases, including C3 glomerulopathy, IgA nephropathy, resistant lupus nephritis and anti-phospholipid antibody syndrome [110-113], but not in cases of AAV.

Castellano and colleagues investigated C1 inhibition in renal ischemia-reperfusion injury using a swine model [114]. The infusion of C1-inhibitor led to reduced deposition of various complement activation products in glomerular and peritubular capillaries, and reduced the number of infiltrating inflammatory cells. Several clinical trials of C1 inhibition in renal transplantation are ongoing [(NCT01147302, NCT01134510 and NCT02134314)].

Paixão-Cavalcante and colleagues [115] reported a humanized monoclonal antibody binding to C3 that inhibited C3 cleavage by the nephritic factor-stabilized convertase. Zhang and co-workers [116] employed soluble CR1 therapy in C3 glomerulopathy noting that it prevented the dysregulation of the alternative pathway C3 convertase.

Blocking of C5aR has been regarded as a novel therapeutic target for the treatment of patients with AAV. A multicenter phase 2 randomized, double-blinded placebo-controlled trial led by the EUVAS evaluated the efficacy and safety of CCX168 (avacopan), a small molecule that blocks CD88 (ClinicalTrials.gov Identifier: NCT01363388) among 67 patients randomly divided into three arms: (1) prednisone 60 mg/day; standard of care control, (2) CCX168 30 mg twice a day plus prednisone 20 mg/day; and (3) CCX168 30 mg twice a day without prednisone. All patients received intravenous cyclophosphamide (15 mg/kg per 2 to 4 wks) or rituximab (375 mg/m² intravenous weekly for 4 weeks). The primary end point at 12 weeks was reached in 70% of patients in the control group, 86% of patients in the reduced-steroid group, and 81% of patients in the avacopan plus placebo group, demonstrating noninferiority for both avacopan groups. There were no apparent differences in the response rates with respect to disease category or ANCA type. However, assessment of the change in BVAS and urinary albumin to creatinine ratio suggested that patients in the avacopan groups had a more rapid and consistent improvement in the study parameters by 4 weeks. Quality-of-life indicators were improved with the steroid-free protocol. The incidence of total and serious adverse events was similar in the three arms suggesting that C5a receptor inhibition with avacopan was effective in replacing high-dose glucocorticoids in treating vasculitis [117]. A phase 3 randomized trial was launched (ClinicalTrials.gov Identifier: NCT02994927) to include patients with AAV and eGFR $\geq$ 15 ml/min/1.73 m² with sustained remission as an end-point.

Other agents that target complement include TP10, which is a C3 soluble complement receptor; and two inhibitory peptides of C3: AMY-101 and compstatin; and small molecule factor D inhibitors to block complement activation. Although there are trials of the treatment of C3 glomerulopathy, TMA and IgA nephropathy, there are none so far in AAV [118].

CONCLUSION

In conclusion, activation of the complement system, especially the alternative pathway, plays a central role in the development of AAV. Among various components of the

complement system, C5a plays a central role priming neutrophils to undergo the respiratory burst with degranulation and release of NETs in the presence of ANCAs, and contributing to the development of systemic vasculitic lesions. The stimulation of neutrophils with C5a in conjunction with ANCAs leads to the release of TF-bearing microparticles and NETs that subsequently activate the coagulation system and generate thrombin. Neutrophils, ANCA and complement system form a positive feedback loop and lead to the development of AAV. The inhibition of complement, especially C5a, is a promising approach for remission induction in AAV. However, whether the same mechanism can also maintain long term remission through control of neutrophil activation remains to be explored.

Chapter 198

EXPERIMENTAL AUTOIMMUNE VASCULITIS: INSIGHTS INTO HUMAN VASCULITIS USING ANIMAL MODELS

Alan D. Salama*, MA, PhD and Mark A. Little, PhD

UCL Centre for Nephrology, London and Trinity Health,
Kidney Centre, Trinity College, Dublin, Ireland

ABSTRACT

Over the last decade several different experimental models have been described that try to recapitulate the clinical features of ANCA associated vasculitis. Although all are limited to some extent in their ability to mirror human disease, together they have provided important and sometimes unexpected insights into disease pathogenesis, as well as new avenues for therapeutic innovation.

Rodent models of both MPO-, and more recently, PR3-ANCA associated vasculitis have replicated some of the clinical features found in affected patients with ANCA-associated vasculitis (AAV), notably with pulmonary and renal involvement. The vast majority of successful work in this field has concerned MPO-AAV, yet there remains the need for a better model for aspects of PR3-AAV, including the granulomatous lesions found in granulomatosis with polyangiitis, and the relapsing nature of the illness. By virtue of the means by which they are induced and their time course, such experimental animal models have not replicated the complex and varied human disease AAV phenotype. However, the effector pathways and the final organ damage appear very similar to those found clinically, allowing many conclusions to be drawn regarding disease etiology. This chapter reviews the salient experimental animal models that replicate the vasculitic lesions in human AAV. Further refinement of these models may yield the full spectrum of the human condition, providing insight regarding organ tropism and therapeutic targets for disease subtypes.

Keywords: vasculitis, ANCA, animal, models

INTRODUCTION

Anti-neutrophil cytoplasm antibodies (ANCA) are associated with diseases characterized by relapsing necrotising vasculitis of small calibre blood vessels, frequently involving the kidneys and lungs respectively leading to pauci-immune glomerulonephritis and pulmonary capillaritis.

Many organs may be affected and, as a result, the conditions cause significant morbidity and mortality. The precise disease triggers are not known, but clinical associations with infection have been reported, with experimental data implicating altered responses to microorganisms as potentially important initiators of autoimmune responses.

ANCA are directed towards two autoantigen, proteinase 3 (PR3) and myeloperoxidase (MPO), found in neutrophil granules and monocyte lysosomes that are involved in innate immune responses to infection, while the clinical significance of other proposed ANCA targets, including lysosome associated membrane protein (LAMP)-2 [1] and moesin [2] remain to be completely characterised. The ANCA-associated vasculitides (AAV) are more common in older age and although they can be treated with immunosuppressive therapies, the disease relapses in up to 50% of treated patients and with re-treatment, there is the increased likelihood of treatment related adverse events.

Animal models of experimental autoimmune vasculitis (EAV) have been developed to dissect the pathological basis of disease, to understand the role of ANCA in the etiopathogenesis of AAV, and to replicate the clinical features. The use of murine models has been favoured because they allow the use of genetically altered animals so that key molecules and pathways involved in pathogenicity can be investigated.

The most novel insight gained from such an approach was the discovery the importance of the alternate complement pathway employing passive anti-MPO antibody transfer in C5 and factor B deficient animals [3], a finding that later prompted a therapeutic trial targeting complement C5a receptor as adjunctive therapy in patients with AAV and renal disease.

Development of adequate models has taken considerable time, with many attempts and refinements over the years. There remain major deficiencies in modelling granulomatous PR3-AAV, relapsing disease overlap syndromes and non-pulmonary-renal involvement such as cardiac, neurological and gastrointestinal disease.

Moreover, the impact of age and immune senescence, infectious triggers, and latent viral infections on disease susceptibility and initiation need further exploration. The inability to model PR3-AAV in mice is in part due to differences between human and rodent neutrophil PR3 expression.

These important omissions and differences should lend some caution to translating the findings from one animal model to all forms of human AAV. PR3-and MPO-AAV may have certain common features, such as the occurrence of pauci-immune glomerulonephritis and pulmonary capillaritis, but they also display many diverse characteristics that translate into important differences in disease phenotype and outcome.

These in turn influence the long-term clinical management. Moreover, genetic studies that demonstrate the differing molecular associations of PR3- and MPO highlight the necessity of considering the two entities separately.

MODELS OF MPO-AAV

There have been many historical attempts at developing models of MPO-AAV, but most have failed to mirror the clinical findings, as they were associated with significant immune complex deposition, a major deviation from the pauci-immune characteristics of clinical disease. Spontaneous models of crescentic nephritis and vasculitis characterised by the presence of circulating MPO-ANCA have been reported, for example the spontaneous crescentic glomerulonephritis/Kinjoh (SCG/Kinjoh) mice. However, they are not pauci-immune and have an array of other autoantibodies besides MPO-ANCA [4]. Significant advances were made in this field through use of knockout and genetically manipulated mice strains, in particular rat strains inherently susceptible to glomerulonephritis. Those strategies included the passive transfer of pathogenic antibody, which proved useful in modelling the acute vascular injury response, and active immunization with MPO that resulted in activation of both humoral and cellular immune elements, consequently providing more insight into the adaptive autoimmune response and potential responses to novel therapies.

Murine Models

Xiao and colleagues [5] developed an acute passive transfer model using purified antibody or splenocytes taken from MPO-deficient mice immunized with purified murine MPO. This took advantage of the allo-immune response to MPO in MPO-deficient mice, generating antibodies and lymphocyte responses that were sufficiently potent to induce disease. Anti-MPO antibodies injected into wild type or RAG-deficient recipient mice led to development of necrotizing pauci-immune glomerulonephritis, and in some cases, pulmonary capillaritis over 6 to 13 days. It was further noted that splenocytes transfer recipients developed glomerular immune deposits, whereas antibody transfer recipients remained pauci-immune. Virtually all subsequent work was conducted with the model that used a passive transfer strategy even though the degree of induced disease was much milder.

The development of glomerulonephritis using cell transfer was dependent on B-cells rather than T-cells, and required the presence of neutrophils [6]. This model was replicated at other centres and further refined to produce augmented disease through the addition of lipopolysaccharide (LPS) [7], mimicking the effects of infection, and exacerbating autoimmunity via toll like receptor (TLR) activation and up-regulation of tumour necrosis factor- α . Further investigation of the model using different mouse strains, demonstrated that the genetic background of the mice had a profound effect on the severity of the model, with 129S6 mice developing worse crescentic disease than C57BL/6 mice in which the model was first generated [8], and with augmented pulmonary-renal disease in the absence of the inhibitory Fc γ -II receptors [9]. That model demonstrated a critical role for alternative, but not classical, complement components in disease induction [3], which was surprising given the lack of clinical evidence of complement consumption in AAV. Since the available small molecule inhibitors of C5a receptor were only active against the human form of the receptor, Xiao and colleagues [10] adapted the murine anti-MPO transfer model by generating mice transgenic for the human C5a receptor allowing them to test the inhibitor in the murine model and demonstrate its efficacy in reducing renal disease.

A subsequent human trial using this C5a receptor antagonist in treatment of AAV was initiated [11]. Further modifications of this model used a bone marrow transplant approach in which immunization of MPO-deficient mice with murine MPO, were subjected to lethal irradiation followed by transfer of either MPO-expressing or MPO-deficient bone marrow.

MPO expression on hematopoietic cells was necessary for disease induction [12], as only transfer of MPO-sufficient cells resulted in disease manifested as necrotizing glomerulonephritis. With various refinements, this model [5] revolutionised the understanding of the mechanisms of acute anti-MPO induced vascular injury. However, all of the model variations had limitations, as these were not autoimmune in nature, but relied instead on alloimmune responses to MPO. Comparisons of the avidity of alloimmune anti-MPO antibodies and other autoimmune ones formed by immunizing WT mice with MPO have not been reported, although it is suspected that there would be significant differences reflecting the propensity for disease induction with this model compared to previous failed attempts by direct MPO immunization. Furthermore, as with all induced models, they begin downstream of the break in clinical immune tolerance with a pre-formed anti-MPO antibody, restricting some of the potential insights into clinical disease initiation. A slightly different strategy for modelling MPO autoimmunity was adopted by Ruth and co-workers [13]. The investigators [13] immunized C57BL/6 mice with MPO in adjuvant, both human and murine, generating cellular and humoral anti-MPO responses, followed by low dose sub-nephritogenic nephrotoxic serum to induce a local renal immune response within glomeruli. In contrast to the passive MPO model, this technique depended upon T-cell and not B-cell immunity. Effector CD4⁺ cell depletion attenuated crescentic glomerulonephritis and effector cell influx without altering ANCA titers. However, B cell-deficient mice, with no ANCA, still developed severe crescentic glomerulonephritis with accumulation of effector cells [13]. The proposed explanation of the model was that it relied upon deposition of MPO in the glomerular circulation following neutrophil migration and de-granulation in response to deposited nephrotoxic serum. There was in turn a subsequent adaptive cellular immune response towards the deposited MPO already induced by the prior immunization of MPO in adjuvant. This model was used by Gan and colleagues [14] to illustrate the importance of the key Th17 effector cytokine IL-17A. To test whether IL-17A also drives autoimmune delayed-type hypersensitivity in the kidney, the investigators [14] injected MPO into the kidneys of MPO-sensitized mice noting that IL-17A deficiency reduced accumulation of renal macrophages and renal CCL5 mRNA expression, lending support to the clinical findings of elevated IL-17 levels in patients with acute and more severe disease in AAV [15]. This model also demonstrated the importance of innate immune pathway stimulation as a co-stimulus for disease induction as well as the pathogenic role of TLR in initiating autoimmune AAV in a series of experiments in which TLR-2 induced Th17 CD4 cells while TLR-9 directed vasculitis by enhanced Th1 autoimmunity [16]. These observations were likely due in part to the mimicking influence of infection and TLR signalling on development of ANCA autoimmunity and organ related disease leading to glomerulonephritis.

Rat Models

A model of MPO-AAV was developed by immunization of a susceptible Wistar-Kyoto (WKY) rat strain with human MPO, in Complete Freund's adjuvant (CFA).

This approach resulted in generation of MPO-ANCA and MPO-reactive T-cells [17] with development of a crescentic, pauci-immune glomerulonephritis, and pulmonary capillaritis in a proportion of treated animals (Figure 1) [18]. The induced anti-human MPO antibodies cross-reacted with rat MPO, displaying significant homology to the human molecule.

Although ANCA-IgG was not found to transfer disease in this model, it did increase leukocyte-endothelial interaction [19], and clearly showed that the composition of the adjuvant providing the innate immune stimulation and the genetic background of the rat were critical to the determination of severity and disease susceptibility. Lewis rats, which share the same MHC Rt1 locus as the WKY strain, do not develop vasculitis or glomerulonephritis despite achieving similar levels of anti-MPO antibodies, demonstrating that non-MHC genes are important in mediating the pathogenic potential of MPO-ANCA.

The significant genetic differences conferring susceptibility to other forms of glomerulonephritis including nephrotoxic nephritis and anti-glomerular basement membrane disease, in these rats has been described, largely related to differences in macrophage reactivity and Fc receptor activation [20].

The role of certain genetic loci as susceptibility factors in the MPO-AAV model and resulting disease severity was examined using congenic Lewis/WKY animals demonstrating the critical role of chromosome 13 and 16 susceptibility loci in the development of experimental autoimmune vasculitis [21].

While the murine T-cell mediated model implicates deposited MPO directing a delayed type hypersensitivity response within the kidney, it does not appear to be the main mechanism in the rat MPO autoimmune model [18] as there is no evidence of deposited MPO.

Figure 1. Photomicrograph of a single glomerulus from a rat with experimental autoimmune vasculitis demonstrating crescentic change (PAS x400).

Experimental animal models of vasculitis that may be contrived or manipulated to produce the desired phenotype do not necessarily have to be mediated through identical pathways. MPO-ANCA induced in MPO deficient animals by an alloimmune anti-MPO response may be very different from the autoimmune anti-MPO response.

Indeed, it is now appreciated that there is significant heterogeneity in anti-MPO antibodies found in patients with different epitope reactivity and with interference of immune reactive sites under certain circumstances [22]. It would therefore be of interest to investigate the differences between induced anti-MPO antibodies from different rodent models. Epitope differences may contribute to why the model cannot be transferred with anti-MPO T-cells. This may relate in part to the short duration of follow up in comparison to the immunized rat model, which takes four or more weeks to develop similar glomerular lesions.

In the combined anti-MPO/nephrotoxic nephritis model, the anti-MPO response is a recall response in a previously immunized animal.

When considered together, the rodent models demonstrate that vasculitis, as manifested by pulmonary and renal disease, may be induced when a sufficient anti-MPO immunity threshold is achieved. Patients rarely display an exclusively T- or B-cell response, or a uniquely innate or adaptive immune response.

Rather, the observed disease represents the sum of these different pathways. Reductionist models can provide critical insights into individual mechanisms or pathways of disease induction, even though they may be incapable of defining them all. In particular, none of the models currently explains why or how immune tolerance to self-antigens is broken in the first instance, with later destructive anti MPO reactivity.

RODENT MODELS OF PR3-AAV

There have been no spontaneous experimental models in rodents of glomerulonephritis or vasculitis in association with anti-PR3 antibodies, nor PR3-ANCA in association with other autoantibodies. This is likely related to differences between humans and rodents in PR3 and its cellular expression. Despite immunizing rats and mice with combinations of human or murine PR3, chimeric molecules, and demonstrating induction of PR3-ANCA, van der Geld and colleagues [23] were unable to experimentally generate vasculitis. Pfister and colleagues [24] immunized PR3- and neutrophil elastase-deficient mice with murine PR3, transferred the resultant antibodies into LPS-primed mice, and did not observe significant renal or pulmonary pathology. There was a mild increase in panniculitis following intradermal TNF injection and PR3-ANCA transfer compared to controls. Primo and colleagues [25] described the successful transfer of PR3-ANCA producing splenocytes isolated from recombinant murine PR3-immunized autoimmune-prone non-obese diabetic (NOD) mice into naïve NOD-severe combined immunodeficient (SCID) recipients lacking endogenous T-cells and B-cells.

The immunized NOD mice developed PR3-ANCA without apparent disease despite prolonged follow up while the NOD-SCID mice that received PR3-reactive splenocytes rapidly developed signs of disease with vasculitis and necrotizing crescentic glomerulonephritis. Moreover, there were no granulomata observed despite significant anti-PR3 immune reactivity; and C57BL/6-RAG mouse recipients of the same splenocytes did not develop disease.

These findings suggested that there were protective mechanisms operating in immunized NOD mice mediated by regulatory lymphocyte populations, while the genetic background and degree of immunodeficiency appeared to play an important role in disease susceptibility. In the successful anti-MPO splenocyte transfer model of Xiao et al. [5], the recipient strain was C57BL/6-RAG2^{-/-} further underscoring the difference between MPO and PR3 immunity. The presence of glomerular immune deposits was not discussed in the report by Primo and colleagues [25]. Their results were of limited applicability to human anti-PR3 associated AAV. Relle and colleagues [26] successfully created transgenic FVB mice that expressed human PR3 into which they infused monoclonal anti-PR3 antibodies.

However, expression of PR3 was under the control of the promoter meaning that protein was expressed only in glomeruli. Not surprisingly, they [26] did not detect any pathological features of vasculitis as the current AAV paradigm for pathogenesis proposes interaction of the antibody with PR3 on neutrophils and monocytes, not glomerular cells, with resultant activation of these cells and bystander microvascular injury.

One hallmark of ANCA vasculitis is that the glomerular lesions are pauci-immune, meaning that there is little or no local glomerular immune complex formation. One wonders whether different results would have been obtained if human PR3 had been expressed on the surface of myeloid cells, although it is likely that one would need to link it to other membrane bound proteins such as CD177 to see the intracellular effect of ANCA binding.

Little and co-workers [27] recently described the use of humanized immunodeficient NOD SCID IL2-receptor knockout mice, which received human hematopoietic stem cells and developed a human-mouse chimeric immune system. These mice developed mild glomerulonephritis and lung hemorrhage without evidence of granulomata following passive transfer of PR3-ANCA containing IgG derived from patients with severe systemic vasculitis.

These exciting developments open the way for further investigation of pathogenic mechanisms and definition of immune requirements for the induction of anti-PR3 associated vasculitis.

CONCLUSION

By inducing an abnormal immune response to MPO, investigators have succeeded in generating pathological changes in mice and rats that mimic human MPO-ANCA-AV, although most models exhibit much milder disease than that usually seen in patients. Passive transfer of pathogenic antibody has proven a useful tool for investigating the molecular mechanisms underlying acute vascular injury, and supports the concept that anti-MPO antibodies, in conjunction with neutrophils, are capable of inducing such injury.

This provides a rationale in support of therapeutic strategies that aim to remove these antibodies, such as plasma exchange and rituximab.

Active immunization of mice and rats with MPO has provided a more accurate model of an immune response that involves both cellular and humoral immunity allowing investigation of the role of T-cells, specifically those of the Th17 axis that have been implicated in autoimmune disease. Such active immunization strategies are well suited to long-term therapeutic trials of novel agents, although for this to be truly useful, the disease phenotypes of the particular models will need to be more severe.

Table 1. Models of MPO- and PR3-ANCA associated vasculitis and glomerulonephritis

Model	Induction protocol	Proposed Mechanism	Organs affected	Severity	Comments/Reference
Passive anti-MPO Ab transfer	Anti-MPO-Ab induced in MPO-deficient mice and transferred into LPS primed recipients	ANCA induced neutrophil degranulation, dependent on B-cells and alternative complement activation	Lungs, kidneys	Mild crescentic GN, more severe in 129 strain	Noticeable strain effect
MPO-ANCA DTH model	MPO-immune response induced by immunization of MPO in CFA, followed by subnephritogenic dose of nephrotoxic serum in C57BL/6 mice	Delayed type hypersensitivity response to planted nephrotoxic antigen, allowing neutrophil degranulation and deposition of MPO target. T-cell, but not B-cell dependent.	Kidney only	Mild crescentic GN	Dosing and timing of nephrotoxic serum critical
Experimental autoimmune vasculitis	Immunization of WKY rats with human MPO in CFA	Induction of anti-MPO Ab and T- cells.	Lungs, Kidney	Mild crescentic GN	Dose dependent effect of MPO on disease severity
PR3-ANCA vasculitis in NOD mice	Immunization of NOD mice with recombinant PR3 in CFA and passive transfer of splenocytes into NOD-SCID mice	Development of PR3-ANCA and presumably PR-3 specific B-cells. No comment on T-cell reactivity	Lungs, kidneys	Crescentic GN	NOD-RAG recipients did not develop disease while NOD-SCID did, suggesting that significant other factors apart from PR3 reactive splenocytes play a role.
PR3-ANCA vasculitis in humanized mice	Generation of chimeric human-mouse immune system by transfer of human CD34+stem cells to NOD SCID IL2-receptor KO mice followed by passive transfer of human PR3-ANCA	Generation of myeloid and lymphoid chimerism providing human neutrophil and monocyte targets for PR3-ANCA	Lungs, kidneys	Mild proliferative GN	

Modelling of anti-PR3 associated disease in animals is significantly less advanced and, by virtue of the differences in PR3 structure and expression between mice and men, will probably rely in the future on the use of humanized and transgenic *in vivo* systems. The generation of an animal model incorporating both anti-PR3 associated vasculitis and granuloma formation, as well as, relapsing disease, cardiac, gastrointestinal and neurologic disease remains a major challenge for the next decade.

ABSTRACT

The generation of large-scale genotyping data is substantially increasing the understanding of human diseases with a complex genetic component. Such data analysis has been applied to the vasculitides, which are characterized by inflammatory damage of the blood vessels. They show a very complex etiology in which both environmental and genetic factors seem to contribute to the predisposition and clinical phenotype of the disease. During the last decade, a large number of genetic studies, genome-wide association studies in some cases, have been performed on vasculitides and, strikingly, most of the identified risk loci shared susceptibility factors amongst them. This reinforces the idea that some immunological pathways are key players in the major hallmarks of these diseases.

* Corresponding Author's Email: miguelaggay@hotmail.com.

However, since the current knowledge of the genetic basis of the vasculitides is often based on studies performed in reduced populations, further collaborative studies on larger cohorts are required to provide the last pieces of the genetic puzzle underlying vasculitides, giving us a better perspective of their etiopathogenesis and allowing novel approaches for the development of more effective therapies.

INTRODUCTION

Vasculitides present a complex etiology in which both environmental and genetic factors appear to influence the development and progression of disease. The genetic component of these disorders is supported by the identification of an increased risk among first-degree relatives of affected patients and monozygotic twins. For most vasculitides familial aggregation has been described in case reports or small series without quantification. In the absence of family studies, differing prevalence of these diseases in different ethnic groups supports the existence of important genetic components.

Two main approaches, candidate gene studies and high-throughput genotyping, including genome-wide association studies (GWAS), have been used to identify disease-associated genes in complex diseases both of which involve genotyping of genetic variations, mainly the single-nucleotide polymorphisms (SNP) in cases and controls. Until recently, all genetic studies in vasculitides were designed as candidate gene studies, examining a SNP or a set of polymorphisms within certain *loci* with a potential role in a particular phenotype or disease. In these studies, the selection of a candidate gene or genomic region was based on its biological function or its location in a region implicated by previous associations or linkage studies. In contrast to candidate gene studies, the GWAS approach, in which millions of polymorphisms are analyzed across the whole genome, is unbiased and it does not require prior hypotheses about the type of genes or polymorphisms most likely to be associated with the phenotypes of interest. The recent publication of GWAS in vasculitides has increased the understanding of potential underlying genetic mechanisms. Moreover, the two methodologies have shown that the human leukocyte antigen (HLA) region harbors the strongest genetic contribution to the pathophysiology of vasculitides. This genomic region occupies a large segment of DNA extending about 3.6 megabases on the short arm of chromosome 6, and containing hundreds of genes involved in immune function.

This chapter summarizes the genetic aspects of vasculitides giving an overview of the recent progress in the elucidation of their genetic component. Two Chapel Hill Consensus Conference (CHCC) nomenclatures, one in 1994 and a Revised version in 2012 [1, 2], provided consensus on nosology and definitions for the commonest forms of vasculitis in adults based upon the caliber of vessels involved. The Pediatric Rheumatology European Society (PRES), European League against Rheumatism (EULAR), and the Pediatric Rheumatology International Trials Organization (PRINTO) proposed specific classification criteria, as well as, clinical, laboratory and radiographic characteristics for the commonest childhood vasculitis syndromes, based upon vessel size [3, 4], similar to the 2012 Revised CHCC nomenclature [2]. These overlapping nomenclatures form the basis for the definition of most recent cohorts of vasculitides to which reference is made in this chapter.

LARGE VESSEL VASCULITIS

Giant Cell Arteritis

Increasing knowledge suggests that giant cell arteritis (GCA) has an important genetic basis [5]. Familial aggregation with sharing of HLA alleles has been reported for GCA from several decades ago [6-13].

However, until recently most studies were performed in unreplicated Spanish and Italian populations [14] usually with small sample sizes. Despite these initial limitations, GCA was always considered as one of the best examples of vasculitis in which a genetic influence has been implicated in both disease susceptibility and severity. As discussed below, the establishment of international collaborative groups and the recent large scale genetic studies performed in this type of vasculitis have represented a turning point in the elucidation of its pathogenic mechanisms [15, 16].

HLA Association

Early candidate gene studies identified HLA class II region as the most consistent susceptibility *locus* for GCA. Carriage of HLA-DRB1*04 alleles (specifically DRB1*0401 and DRB1*0404) was proposed as the main contributor of the GCA genetic component [17-29]. An increased predisposition for the development of visual manifestations as well as resistance to corticosteroid treatment in GCA patients was related to the presence of HLA-DRB1*04 allele [26, 30, 31], which gave an idea of the crucial role that this allele may have in GCA pathophysiology. On the other hand, associations between GCA and alleles of the HLA class I region, including HLA-B*15, HLA-A*31, HLA-B*8, HLA-Cw3 and HLA-Cw6, as well as the nearby gene MHC class I polypeptide-related sequence A (*MICA*), encoding a stress-inducible transmembrane molecule, were also reported [17, 32-34], although not as consistent as those of the class II region.

The publication of the first large scale genetic study of GCA in 2015 definitively represented a considerable leap in the understanding of the genetic contribution of the HLA system to the susceptibility of this form of vasculitis. In collaboration with the UKGCA Consortium, the Vasculitis Clinical Research Consortium (VCRC), and many other research groups and hospitals from Europe, our group carried out a dense fine-mapping of immune-related *loci* using the Immunochip platform, a custom high-density genotyping array designed for immunogenetics studies [35]. One of the advantages of this chip is the presence of a high SNP coverage in the HLA region, which allows imputation of two- and four-digit classical HLA alleles as well as polymorphic amino acids using reference panels [36, 37]. We performed a comprehensive interrogation of the HLA region at the amino acid level using this bioinformatics approach in a total of 1,651 GCA patients and 15,306 unaffected controls. Our results highlighted the class II molecules as the main contributors to GCA risk, specifically HLA-DR β 1 and HLA-DQ α 1. The class I gene *HLA-B* was also associated, but with a considerable lower statistical significance. We proposed a model of 3 amino acid positions that explained most of the HLA association with GCA, which included positions 13 and 56 of HLA-DR β 1 and HLA-DQ α 1, respectively, as well as 45 of HLA-B. All three positions were located at the binding pocket of the protein, suggesting a possible involvement in antigen recognition. The top signal corresponded to presence of histidine at position 13 of HLA-

DRβ1, consistent with the previous associations between GCA and HLA-DRB1*04 classical alleles, as His13 is one of the amino acids that define them [16].

Non-HLA Association

The protein tyrosine phosphatase nonreceptor type 22 (*PTPN22*) gene encodes a tyrosine phosphatase known as LYP that it is expressed mainly in lymphoid tissues and is involved in several signaling pathways associated with the immune response, including the T-cell receptor (TCR) pathway in which LYP plays a central role in its negative control, but also the humoral activity of B-cells. A functional *PTPN22* variant (rs2476601/R620W) has been associated with several autoimmune diseases, representing the clearest example of a common genetic risk factor in autoimmunity [38]. *PTPN22* R620W represented the strongest non-HLA association signal in the Immunochip of GCA [16], which confirmed previously reported observations through the candidate gene approach [39]. This association was initially identified in a large discovery cohort from Spain and subsequently replicated in three European replication cohorts from the United Kingdom (UK), Germany and Norway. It has been demonstrated that the R620W change interferes with the ability of LYP to bind its partner c-src tyrosine kinase (CSK) [40] which prevents the formation of the complex between both proteins and the suppression of the T-cell activation.

The first GWAS performed in GCA was published on 2017. The involvement of the European Vasculitis Genetics Consortium (EVGC) allowed the recruitment of three additional cohorts to the first case/control set of the Immunochip, comprising a total of 2,134 GCA patients and 9,125 controls from 11 populations of European origin (Spain, Italy, UK, USA, Canada, France, Germany, Norway, The Netherlands, Ireland and Switzerland) [15]. The analysis of a total of 1,844,133 genetic markers across the whole genome led to the identification of two genes involved in angiogenesis and vascular remodeling as the most relevant non-HLA genetic factors of GCA, i.e., plasminogen (*PLG*) and prolyl 4-hydroxylase subunit alpha 2 (*P4HA2*). The first one encodes a precursor of both plasmin and angiotatin proteins [41]. The GCA-associated *PLG* variants were predicted to affect their gene expression, which could unbalance the plasminogen/plasmin system favoring a pro-inflammatory environment [15]. On the other hand, *P4HA2* encodes the α subunit of the collagen prolyl 4-hydroxylase, a hypoxia responsive enzyme involved in collagen biosynthesis [42]. Some of the *P4HA2* alleles that conferred risk to GCA were predicted to alter *P4HA2* expression in lymphoblastoid cells and the aorta [15].

Different lines of evidence clearly suggest that Th17 cells are crucial players in GCA development. They include both presence of this cell type and increased levels of IL17 in the vascular lesions of GCA patients. Interestingly, corticosteroid therapy seems to be more effective on Th17 cells than on Th1 cells under a GCA background [43-45]. Consistent with these observations, associations between GCA and *IL17A* gene polymorphisms were described in a candidate gene study performed on 2014 [46].

The NLR family pyrin domain containing 1 (*NLRP1*) gene, another autoimmune disease-associated locus, was also confirmed as a GCA susceptibility gene in a study on Spanish and Italian populations [47]. This gene encodes a cytoplasmic protein involved in the assembly of the inflammasome that activates caspases 1 and 5 which results in the activation of proinflammatory cytokines. As expected, considering its inflammatory nature, different cytokines have been implicated in GCA pathogenesis. Amongst them, the interleukin 10 (*IL10*) gene represents the most consistent association [48, 49]. This gene encodes an anti-

inflammatory Th2 cytokine with pleiotropic effects in the immune system, including the negative control of Th1 cytokines such as interferon gamma (IFN- γ), the regulation of the B cell function, and the repression of nuclear factor kappa-light-chain-enhancer of activated B cells (NF- κ B) activity. Two independent studies in Italian [48] and Spanish [49] populations indicated that variation of the *IL10* promoter region may be involved in the pathogenic mechanisms leading to GCA.

Other genes encoding cytokine or cytokine receptors that have been suggested as possible genetic risk factors for GCA: *IL33*, encoding an IL-1 family member with strong immunomodulatory functions; *IL4*, encoding a protein that acts reciprocally with IFN- γ inducing the Th2 immune response; *IL6*, with pleiotropic effects that may exert both pro-inflammatory and anti-inflammatory functions; *IL18*, encoding a pro-inflammatory cytokine with cytotoxic T-cell functions; monocyte chemotactic protein-1 (*MCP1*), encoding a chemoattractant protein for mononuclear cells to the sites of inflammation; regulated and normal T-cell expressed and secreted (*RANTES*), encoding a potent chemotactic factor for immune cells; the *IL2/IL21* region of cytokines important in the correct function of the immune system; IL12 receptor beta 2 (*IL12RB2*), a key player in the inflammatory response; tumor necrosis factor (TNF), encoding a proinflammatory cytokine involved in the regulation of immune cells; and *IFNG*, encoding a key cytokine involved in innate and adaptive immunity against intracellular pathogens and tumor control [50-59].

The possible role of a number of important molecules for the endothelial function in GCA predisposition and severity has been also explored. Although most of the studies were low-powered and without replication, evidence of association was observed for intercellular adhesion molecule 1 (*ICAM1*), encoding a cell surface glycoprotein involved in the interactions between immune and endothelial cells during inflammation; vascular endothelial growth factor (*VEGF*), encoding an important vasculogenic mediator; cytokine-inducible and endothelial nitric oxide synthases (*NOS2A* and *NOS3*), involved in the regulation of the oxidative stress; and matrix metalloproteinase 9 (*MMP9*), encoding an enzyme with proteolytic activity on the extracellular matrix [52, 60-66].

Finally, genes of the innate immunity may also have a role in GCA pathogenesis. Significant associations have been reported for toll-like receptor 4 (*TLR4*), implicated in signal transduction events induced by lipopolysaccharide from Gram-negative bacteria; Fc gamma receptor 2A and 3A (*FCGR2A* and *FCGR3A*), encoding cell-surface proteins of the immunoglobulin superfamily; and myeloperoxidase (*MPO*), an important gene in the neutrophil function [67-69]. However, all these associations require confirmation in larger and independent cohorts.

Takayasu Arteritis

A few candidate gene studies exploring the possible role of genetic polymorphisms in Takayasu arteritis (TAK) were performed before the publication of three recent large scale analyses, i.e., a genome scanning of exonic regions in a Japanese cohort [70], an Immunochip in Turkish and North Americans [71], and an unbiased GWAS also in Turkish and North Americans [72].

HLA Association

Different genetic studies showed that *HLA-B* alleles are involved in the disease susceptibility. Specifically, *HLA-B*5201* was associated with TAK in multiple cohorts of diverse ethnicities including different populations from Asia and Mexico [73-78], which was confirmed in the GWAS of Japanese [70]. However, this association was not observed in North American and Arab populations [79, 80]. In the former [79], a positive correlation of *HLA-DR4/MB3* and a strongly negative association of *HLA-DR1* with TAK were reported, whereas in Arab patients [80] the association with this region was narrowed down to *HLA-A2*, *HLA-A9*, *HLA-Bw35* and *HLA-DR7* alleles.

Studies on polymorphisms of the gene encoding the human complement factor 4 (C4), located at the class III region of the HLA, showed a significantly high frequency of C4A2 and C4BQ0 allotypes in strong association with *HLA-Bw52* [81]. Furthermore, the analysis of *MICA*, situated between the class I and class III regions, revealed an association between the *MICA-1.2* allele and TAK, even in the absence of *HLA-B52* [82].

A subsequent study [83] in which five microsatellites, C1-2-A, MIB, C1-4-1, C1-2-5 and C1-3-1, around the *HLA-B* and *MICA* genes were analyzed in Japanese TAK patients, suggested two different disease-susceptibility loci for TAK, one that mapped near the C1-2-A locus, and another closely linked to the *HLA-B* gene. Very recently, the *MICA* and the *HLA-DQB1/HLA-DRB1* regions were also described as TAK risk factors in the Immunochip study on Turkish and American cohorts [71].

Non-HLA Association

The most consistent associations with TAK outside the HLA region rely on *IL6*, the leukocyte immunoglobulin like receptor B3 (*LILRB3*) region, *IL12B* and the *FCGR2A/FCGR3A* loci. The two first loci were identified in the GWAS on 2015 [72]. *IL6* was previously suggested as a TAK locus by candidate gene studies [84]. This gene encodes an important cytokine with key roles in different aspects of the immune response, including the differentiation of Th17 cells and regulatory T-cells (Treg). Consistent with this association, an altered production of several cytokines, including IL-6, IL-2 and IL-12, were detected in TAK patients. Increased levels of IL-6 and IL-12 and a lower number of CD3+ T cells producing IL-2 in the active phase of the disease were described [85-87]. Polymorphisms of the genes encoding these cytokines were correlated with altered protein levels [84, 88-93]. Regarding the second non-HLA signal of the GWAS, *LILRB3* is located in an immune-regulatory gene rich region on chromosome 19q13.4, which contains genes encoding for killer immunoglobulin-like receptors (KIR), leucocyte immunoglobulin-like receptors (LILR), and leucocyte-associated immunoglobulin-like receptors (LAIR). Remarkably, the top marker within the associated region was related to reduced transcription levels of multiple genes including *LILRB3* [72]. On the other hand, *IL12B* showed a high association peak in both the exome screening study and the Immunochip, whereas *FCGR2A/FCGR3A* was identified as a susceptibility region for TAK in the Immunochip [70, 71].

Two genes encoding members of the IL-1 cytokine family, *IL1B* encoding IL-1 β , and IL-1 receptor antagonist (*IL1RN*) encoding IL1-Ra, were involved in TAK predisposition [94]. IL-1 may mediate the inflammatory response occurring in the vascular wall by activating monocytes and expression of adhesion molecules on endothelial cells, inducing secretion of

other inflammatory mediators. IL-1Ra inhibits the activities of IL-1 α and IL-1 β , and modulates a variety of IL-1 related immune and inflammatory responses.

Functional and genetic studies [95-97] have reported an implication of both genes in cardiovascular disease, a common feature in TAK patients. In addition, different polymorphisms of *IL1B* and *IL1RN* were associated with TAK in the Mexican population [94], which suggests a crucial role of IL-1 in the vasculitis lesions of TAK.

Genes encoding cardiovascular-related molecules may also play a role in TAK development [98, 99]. For instance, paraoxonase 1 (*PON1*), a high density lipoprotein (HDL)-associated enzyme involved in prevention of lipid peroxidation, was diminished in activity in TAK patients suggesting a possible role of these lipoproteins in TAK vascular dysfunction [98]. A recent study in the Mexican population [99] suggested that variation within *PON1* may be involved in TAK susceptibility by influencing development and progression of arterial damage.

MEDIUM VESSEL VASCULITIS

Kawasaki Disease

A large number of genetic studies have been conducted in order to unravel the genetic component of Kawasaki disease (KD) [100] focused mainly on candidate genes implicated in the immune response. In addition, since the most serious complication of KD is the development of coronary artery lesions (CAL), the role of cardiovascular-related *loci* has been extensively studied. However, sample sizes have often been insufficient and only a few associations have been replicated in subsequent studies [100].

In the last years, six GWAS on KD have been published [101-106]. This approach has represented an important step forwards to the understanding of the genetic basis of this vasculitis.

HLA Association

The involvement of the HLA region in KD is controversial. Association between KD and HLA class I molecules was evidenced [107-111], but the results were inconsistent. Early studies reported an association between HLA-Bw22 now called Bw54, and KD in the Japanese population [107, 108], whereas the HLA-Bw51 and HLA-B44 alleles were predominantly associated with the disease in Caucasians [109-111]. On the contrary, in a recent GWAS [105], a significant association of HLA class II region with Japanese KD patients was identified. Specifically, the strongest association signal was observed at the intergenic region between HLA-DQB2 and HLA-DOB (rs2857151). This association was replicated in a subsequent Han Chinese study [112]. A suggestive association signal was also observed in the HLA class III region (rs2516390), close to the nuclear factor of kappa light polypeptide gene enhancer in the B-cell inhibitor-like 1 (*NFKBIL1*) and lymphotoxin alpha (*LTA*) genes.

However, no significant associations of HLA alleles were documented in other published GWAS. Thus, a consistent allele or haplotype of HLA conferring KD susceptibility has not yet been identified.

Non-HLA Association

Several genes have been suggested to play a role in KD susceptibility through candidate gene studies [113-125]. Susceptibility *loci* include 1) cytokines and their receptors, such as *IL4*, *TNF*, the chemokine (C-C motif) receptor 2-3-5 (*CCR2-CCR3-CCR5*) gene cluster which encodes three receptors of different chemokines that play a critical role in the selective accumulation and activation of inflammatory cells in affected tissues; 2) genes encoding cardiovascular-related molecules, including *VEGF* implicated in the predisposition to this vasculitis and CALs development in different populations, and *MMP3*, 9, 13 also associated with CAL; and 3) genes involved in innate immunity, like mannose binding lectin 2 (*MBL2*) involved in complement activation and associated with an increased risk of CAL, and *NLRP1* involved in the inflammasome assembly.

Potential *loci* implicated in KD susceptibility in Japanese families include the 19q32.2 and 4q35 regions. Subsequent fine-scale studies [126] of the 19q32.2 region have led to the identification of functional polymorphisms of the inositol 1,4,5-triphosphate 3-kinase C (*ITPKC*) gene significantly associated with the susceptibility to KD, with particular risk of developing CAL in both Japanese and Caucasian patients. This gene encodes one of the three isoenzymes that phosphorylate inositol 1, 4,5-trisphosphate (IP3) acting as an important molecule in the regulation of T-cell activation.

Regarding the 4q35 linkage region, several immune genes have been mapped around the peak of linkage, including the IFN regulatory factor 2 (*IRF2*), *TLR3* and caspase 3 (*CASP3*) that play central roles in apoptosis. A subsequent positional candidate gene study [127] in Japanese and Americans of European ancestry subjects identified a functional *CASP3* variant that altered the gene expression in immune effector cells. This SNP was shown to influence KD susceptibility. Both the *ITPKC* and *CASP3* associations with KD were replicated in the Taiwanese population [128, 129].

More recently, based on previously published suggestive linkage signals at chromosome 12q24 [125], a missense SNP located within exon 2 of the calcium release-activated calcium modulator 1 (*ORAI1*) gene was described as a risk factor for KD in the Japanese population. This gene encodes a membrane calcium selective ion channel involved in T-cell activation through the Ca^{2+} /NFAT pathway. Strikingly, the frequency of the risk allele is more than 20 times higher in Japanese compared to that in Europeans, suggesting that *ORAI1* may be related to the differential KD incidence between populations of Asian and European descent [130].

In 2009, the first GWAS performed on KD Caucasian patients [101] led to the identification of eight putative novel susceptibility *loci*. Five of these genes, calcium/calmodulin-dependent protein kinase II delta (*CAMK2D*), CUB and Sushi multiple domains 1 (*CSMD1*), ligand of numb-protein X1 (*LNK1*), N-acetylated alpha-linked acidic dipeptidase-like 2 (*NAALADL2*), and t-complex 1 (*TCP1*), formed a functionally close network of 35 genes defined in the Ingenuity database (Ingenuity Systems, Redwood City, CA, www.ingenuity.com). This gene network suggests possible mechanisms by which one or more infectious triggers may lead to deregulated inflammation and apoptosis, and cardiovascular pathology.

In 2011, another GWAS [103] was conducted in a Korean population, and two novel susceptibility signals were identified: a SNP close to the Dab reelin signal transducer homolog 1 (*DAB1*) gene associated with KD predisposition, and an intronic variant of pellino E3 ubiquitin protein ligase 1 (*PELI1*) gene which is involved in the TLR pathway associated

with CAL development. The first GWAS in the Han Chinese population [106] identified several putative genetic variants associated with KD susceptibility, although none of them reached GWAS statistical significance due to a limited sample size.

The highest peaks included three SNP close to coatomer protein complex beta-2 subunit (*COPB2*) gene, one located within the intronic region of endoplasmic reticulum amino peptidase 1 (*ERAP1*), and six clustered in an area containing immunoglobulin heavy chain variable region (*IGHV*) genes.

A well-powered GWAS [102] in KD patients from different populations of European ancestry (Australia, UK, Netherlands and US) identified two *loci* that exceeded the threshold for GWAS significance. One of them was *ITPKC*, confirming this gene as a risk factor for KD, and a functional polymorphism (H131R, rs1801274) of *FCGR2A*. Finally, both Taiwanese [104] and Japanese [105] groups independently reported GWAS results in 2012 [104, 105]. In both studies, significant associations were observed in the B-lymphoid tyrosine kinase (BLK) region. The most strongly associated polymorphism in the Taiwanese study [104] was in high linkage disequilibrium (LD) with a genetic variant associated with systemic levels of BLK and increased risk of systemic lupus erythematosus (SLE). SNP around cluster domain 40 (*CD40*, a member of the *TNFR* superfamily that potentially contributes to inflammation and autoimmune disease processes through the selection of autoreactive T cells in the thymus and the activation of B- and T- cells) were also associated with KD at GWAS level in both studies. Interestingly, increased cell surface expression of CD40L, the ligand of CD40, and elevated serum levels of soluble CD40L have been detected in KD. On the other hand, the Japanese study also replicated the association of the previously identified *FCGR2A* functional SNP.

On 2016, Shimizu and colleagues [131] performed a pathway-based analysis followed by gene stability selection using the previously published GWAS data of individuals of European ancestry [102]. They identified variants associated with both susceptibility to KD and aneurysm formation within the solute carrier family 8 member A1 (*SLC8A1*) gene, which encoded protein contributes to the regulation of calcium flux and calcium-dependent cellular processes. The results were further replicated in an independent cohort of Japanese origin [131].

Finally, a recent whole genome screening of a 6-member African American family with two affected KD children identified rare compound heterozygous variants in another TLR member, *TLR6*, shared between both affected siblings [132].

Small Vessel ANCA-Associated Vasculitis

Early genetic studies in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), which comprises granulomatosis with polyangiitis (GPA) [Wegener type], microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) (Churg-Strauss type), focused on self-evident candidate genes encoding respective ANCA target antigens, proteinase 3 (PR3) and myeloperoxidase (MPO).

Subsequent studies reported a clear familial aggregation of GPA, with a relative risk of 1.56 for first-degree relatives, which indicated the importance of the genetic component for this disease [133]. In 2012, the 'European Vasculitis Study Group' (EUVAS) conducted the

first GWAS in AAV [134] (including a large cohort of GPA and MPA patients), reporting more consistent associations with the disease, and suggesting genetic distinctions between the clinical entities of AAV that may be associated with ANCA specificity. Subsequently, two additional GWAS were performed by the VCRC (one only in patients diagnosed with GPA and another in a cohort including GPA and MPA cases) [135, 136]. Those studies definitively helped to increase the knowledge on AAV genetics.

HLA Association

Several early low-power studies [137-139] suggested that different HLA class I and class II *loci* might be involved in the predisposition to GPA including HLA-DQw7, HLA-DR3, HLA-DR1, HLA-DR9 and HLA-B50. However, only the HLA DPB1*0401 allele was firmly associated with GPA, although other neighboring *loci* such as ring finger protein 1 (*RING1*), a transcriptional repressor, and retinoid X receptor beta (*RXRβ*), involved in mediating the effects of retinoic acid, may have independent effects [140,141].

HLA-DP also showed the highest association signals in the three AAV GWAS [134-136], with HLA-DPB1*04 as main contributor of GPA risk [135]. Interestingly, the main associations in the HLA region were observed in the subgroup of patients with presence of anti-PR3 antibodies, although there were also associations in the cohort of AAV patients positive for anti-MPO [134]. Hence, it is likely that HLA-DP alleles are a key factor for autoantibody production in AAV, particularly for anti-PR3.

An increased prevalence of HLA-DR4 was also associated with AAV in general, and more specifically with GPA. One study [142] performed in a Dutch population showed that the three subtypes of AAV had a similar HLA antigen distribution, except for HLA-DR1, which was more prevalent in GPA patients, and HLA-DR8, which showed a decreased frequency in EGPA patients in comparison with the other two subtypes. Other evidences suggested that HLA-DRB4 could represent a risk factor specific for EGPA [143].

Non-HLA Association

PRTN3 and *MPO* encode the two major ANCA autoantigens PR3 and MPO respectively. PR3 is a neutrophil intracellular protease that can be also located on the plasma membrane.

It has been proposed that elevated membrane expression of PR3 is involved in progression of chronic inflammatory diseases, including AAV, and that this fact is likely to be genetically determined.

More than one decade ago, the entire coding and promoter sequences of *PRTN3* were analyzed to identify polymorphisms that could influence the pathophysiology of GPA. The genetic variations described in that study [144] included seven SNPs, one amino acid change (Val119Ile), one 84 base pair insertion/deletion (INDEL), and a microsatellite.

Among them, only one SNP affecting a putative transcription factor-binding site (rs62132295, A-564G) was associated with GPA. In the AAV GWAS [134], this *PRTN3* variant was not associated at GWAS level, although a suggestive P-value with GPA but not with MPA was yielded. However, a stronger size effect was observed when the GPA patients were stratified accordingly with the type of autoantibody production instead of the clinically defined syndromes.

Patients positive for anti-PR3 show a stronger association with *PRTN3* rs62132295 than those positive for anti-MPO, when compared with cohort controls. Additionally, the allele frequencies of this SNP also differed considerably between both subsets of patients. Similar

results were observed for the serpin A1 (*SERPINA1*) gene [134], which encodes a serine protease inhibitor known as α 1-antitrypsin whose targets include PR3 that protects tissues against enzymes from inflammatory cells like neutrophils. The Z (null) allele seems to be specifically associated with anti-PR3 presence rather than with the clinical subtypes, since the most significant P-value was obtained when the AAV patients showing this autoantibody were compared against controls. *SERPINA1* was the only *locus* outside the HLA region that reached GWAS significance. The association between this gene and ANCA positivity has been confirmed in many candidate gene studies [145-150]. The autoimmune disease-associated *PTPN22* functional variant R620W was also reported to confer risk to AAV through candidate gene studies [151,152]. Specifically, it was first implicated in the susceptibility to develop GPA [152], and this association was further confirmed in a higher cohort in which both GPA and MPA patients were included [151].

The second GWAS was performed in North American GPA patients of European descent. The study reported semaphorin 6A (*SEMA6A*), on chromosome 5, as a novel susceptibility marker for GPA. Although the role of semaphorins remains unclear, they seem to control axon guidance, vasculogenesis, cardiogenesis, osteoclastogenesis, tumor metastasis, and immune regulation [135]. The same consortium conducted another GWAS in GPA and MPA patients from European origin on 2017, and confirmed *PRTN3*, *SERPINA1* and *PTPN22* as the strongest non-HLA susceptibility genes for this forms of vasculitis [136].

Another gene that has been associated with AAV predisposition is cytotoxic T-lymphocyte associated antigen 4 (*CTLA4*), which encodes a central regulatory molecule expressed on T- cells that inhibits T-cell function and peripheral tolerance. It has been reported that elevated levels of CTLA4 are expressed in GPA patients [153].

In concordance, many studies have described associations of different *CTLA4* polymorphisms with AAV [154-159], thus supporting the idea that *CTLA4* represents another common susceptibility factor in autoimmunity.

There are other genes of the immune system that showed less consistent evidence of association with AAV, and confirmation in independent cohorts is still required [160]. These include, *IL10*, *CD226*, an adhesion molecule expressed on the surface of natural killer cells, platelets, monocytes and T cells; IL2 receptor alpha (*IL2RA*), an important Treg marker; leukocyte immunoglobulin-like receptor A2 (*LILRA2*), an immunoreceptor expressed in immune cells; integrin, beta 2 complement component 3 receptor 3 and 4 subunit (*ITGB2*), which participates in cell adhesion as well as cell-surface mediated signaling; and *FCGR2A/3B* members of IgG receptor family. Except for *SERPINA1*, *PRTN3*, *CTLA4* and *CD226*, none of the above described genetic associations have been confirmed at the 95% significance level in the AAV GWAS [134].

Small Vessel Immune Complex Vasculitis

IgA Vasculitis/Henoch-Schönlein Purpura

Similar to the other vasculitides, the understanding of the genetic background of IgA vasculitis/Henoch-Schönlein purpura (IgAV/HSP) remains elusive, and further research on well-powered cohorts is still needed to unravel the genetic basis and pathogenic mechanisms leading to this vasculitis.

Until the publication of the first GWAS of IgAV/HSP in 2017, the current knowledge of the genetic component of IgAV/HSP was based exclusively on candidate gene studies including genes mainly involved in the immune and inflammatory responses, but also in endothelial function, mechanisms of complement system activation, coagulation and fibrinolysis, and antioxidation [161].

HLA Association

There is a limited number of studies on the HLA region in IgAV/HSP, all of which have been performed in Spanish, Italian and Turkish populations [161, 162]. In relation to the HLA class II region, an association of the HLA-DRB1*01, HLA-DRB1*07, and HLA-DRB1*11 alleles with IgAV/HSP was first reported in Italy [163] and subsequently confirmed in independent cohorts from Spain [164, 165] and Turkish [166]. The HLA alleles DRB1*01 and DRB1*11 increase the risk for the disease onset, whereas DRB1*07 confer a protective effect to the disease. Also, a protective effect against IgAV/HSP development was described in patients carrying the HLA-DRB1*03 haplotype [165].

The publication of the first GWAS of IgAV/HSP confirmed the HLA class II region as the major susceptibility locus for IgAV/HSP. The authors also used the imputation method described in the GCA section to narrow down the HLA association to a region between *HLA-DQA1* and *HLA-DQB1*. As observed in GCA, positions 13 and 11 of the HLA-DR β 1 carried the strongest disease risk [167].

Other HLA class II alleles have been associated with specific IgAV/HSP clinical characteristics in Turkish cohorts [166] including HLA-DRB1*14, significantly reduced in IgAV/HSP patients with joint involvement, and HLA-DRB1*13, increased in IgAV/HSP patients with nephrotic proteinuria. An association between HLA class I alleles and IgAV/HSP have been also reported, although they remain controversial.

In relation to the class I region, HLA-B35 was first described as a susceptibility factor for nephritis development in IgAV/HSP patients from Spain [168], whereas this allele was subsequently associated with increased risk of the overall disease in a Turkish cohort [169]. The study on IgAV/HSP patients from Turkey [169] also suggested that the presence of the antigens HLA-A2, HLA-A11, and the absence of HLA-A1, HLA-B49, and HLA-B50, influenced IgAV/HSP predisposition. In a recent study, López-Mejías and collaborators [170] reported an association between HLA-B*41:02 and predisposition to IgAV/HSP in Spaniards irrespective of the HLA-DRB1 status.

In addition, HLA-A3 and HLA-B44 were associated with joint involvement, and HLA-A1, HLA-B56, and HLA-B58 were associated with disease severity.

Regarding class III, there is evidence of association between the *C4* locus (involved in the clearance of immune complexes) and IgAV/HSP [171, 172].

Non-HLA Association

In relation to genes involved in inflammatory pathways, polymorphisms of *IL1RN*, *IL8* and *IL1B* have been shown to influence renal involvement in IgAV/HSP patients of European origin [173-176]. Interestingly, a SNP of *IL1B* has been recently described as a potential marker of severe renal manifestations and renal sequelae in patients with IgAV/HSP from Spain [177]. On the other hand, a promoter polymorphism of the *TGFB1* gene and a non-synonymous variant of the Mediterranean fever gene (*MEFV*) has been also associated with susceptibility and severity of IgAV/HSP in Chinese children [178, 179]. Regarding *MEFV*,

this gene encodes a protein known as pyrin that is an important modulator of innate immunity. The name of the gene is based on the fact that variations within this *locus* are related to the phenotype of the Mediterranean fever (a hereditary periodic fever syndrome). Interestingly, a connection between *MEFV* mutations and IgAV/HSP has been suggested [179-181].

Molecules involved in the endothelial function could be also important players in IgAV/HSP. Several studies [182-186] have explored the role of an INDEL polymorphism in the angiotensin I converting enzyme (*ACE*) gene, which is involved in the control of the blood pressure, with contradictory results. Some of them [182-184] suggested that the presence of the deletion may increase the predisposition to IgAV/HSP, while others did not find evidence of association with the disease [185, 186].

Another member of the rennin–angiotensin system, the angiotensinogen (*AGT*) gene has been also suggested to be involved in HPS pathophysiology [184].

On the other hand, a CCTTT repeat polymorphism within *NOS2A*, involved in the metabolism of nitric oxide as indicated before, was associated with IgAV/HSP predisposition and nephritis presence in a cohort from northwest Spain [187]. Similarly, genetic polymorphisms of the *VEGF* gene have been suggested to have a potential implication in the development of nephritis in patients with IgAV/HSP [188, 189].

Other *loci* involved in IgAV/HSP susceptibility or nephritis development include *CTLA4* and *PON1* (which inhibits T cell function and regulates the formation of oxidized lipoproteins, respectively, as indicated before in this chapter) [166, 190].

VARIABLE VESSEL VASCULITIS

Behçet Disease

Although the pathogenesis of Behçet disease (BD) is still poorly understood, major contributors of BD genetics have been identified mainly due to the publication of three GWAS conducted in Turkish, Japanese, Korean and Italian populations [191-193], a follow-up study of one of them [194], and a Immunochip in Spaniards [195].

HLA Association

As observed in most autoimmune diseases, the HLA region harbors the highest susceptibility *loci* for BD, specifically the HLA class I region. In this sense, HLA-B51 (in particular HLA-B51*01 and HLA-51*08) represents the most robust genetic association with BD. This association has been confirmed in populations of different ancestry groups since it was first described in the early eighties [191-193, 196, 197]. Subsequently, the HLA-A26 allele was also reported to have an independent contribution to disease predisposition [198]. In the Immunochip study HLA-B51 also represented the primary-association marker for BD, but two independent susceptibility signals, HLA-B*57 and HLA-A*03, were also described. Besides, the authors proposed an amino acid model comprising the position 97 of HLA-B and the position 66 of HLA-A which accounted for most of the genetic risk of the HLA region [195].

However, a recently published analysis of imputed GWAS data from a Turkish cohort [194] evidenced that the HLA-B51 association with BD is explained by a SNP located between the *HLA-B* and *MICA* loci (rs116799036). The authors also identified three additional independent signals within the extended HLA region located at the psoriasis susceptibility 1 candidate 1 (*PSORS1C1*) gene, HLA-F antisense RNA 1 (*HLA-F-AS1*), and HLA-Cw*1602.

Non-HLA Association

The three GWAS and the Immunochip performed in BD [191-193, 195] represented a turning point in the understanding of the genetic contribution of the non-HLA loci to the disease.

One of the most significant associations with BD described to date is *IL10*. This gene was previously suggested as a genetic factor for BD in candidate gene studies [199, 200], and confirmed by the GWAS data on the Turkish [191] and Japanese [192] populations. However, the recent GWAS on Koreans [193] failed to reproduce this finding. As indicated previously in this chapter, this genetic association is shared with GCA and AAV, but also with other autoimmune diseases such as ulcerative colitis, type 1 diabetes or SLE [197].

Another genomic region associated with BD at GWAS level is *IL23R/IL12RB2* [191, 192, 201]. As stated before, the latter gene encodes a subunit of the IL-12 receptor whose expression is regulated by IFN- γ .

This pathway is crucial in the Th1 and Th17 cell differentiation and it is involved in the inflammatory response. On the other hand, IL-23 is another important immunoregulatory cytokine that also promote Th17 function associated with the active intraocular inflammation in BD patients. Shortly before the publication of the two first BD GWASs [191, 192], an association between *IL23R* and BD was reported in the Han Chinese population [201]. Moreover, this gene harbored the strongest non-HLA signal in the Immunochip [195]. Similarly to *IL10*, the association was confirmed using the GWAS methodology in Turkish and Japanese [191, 192], but not in Koreans [193].

In 2013, the GWAS on Koreans [193], which had a lower statistical power than those on Turkish [191] and Japanese [192] cohorts, identified the GTPase IMAP family member (*GIMAP*) cluster, whose members play an important role in T cell function as well as T cell development and selection, as a novel genetic factor for BD. The peak signal outside the HLA region was observed in *GIMAP4*.

Functional studies performed by the authors evidenced that the minor allele of the associated polymorphism led to lower protein activity than the major allele, and that BD patients showed a lower *GIMAP4* expression in CD4 T cells.

Regarding the Immunochip, besides *IL23R*, two additional non-HLA risk loci for BD were established at the genome-wide level of significance, *IL12A* (which encodes a subunit of the heterodimeric cytokines IL-12 and IL-35) and the jerky like (*JRKL*)/contactin 5 (*CNTN5*) region. The function of *JRKL* is unknown, and *CTCN5* encodes a member of the immunoglobulin superfamily involved in the control of cell surface interactions during the development of the nervous system [195].

A large number of additional genetic associations with BD have been suggested through candidate gene studies, although most of them do not rely on consistent results. For example, associated variants have been identified in 1) genes encoding cytokines/chemokines, such as transforming growth factor beta 1 (*TGFB1*), *TNF*, *IFNG*, *IL1A*, *IL1B*, *IL2*, *IL4*, *IL6*, *IL8*,

IL17A, *IL18*, and *MCP1* amongst others [200, 202-217]; 2) genes involved in the endothelial function, including *VEGF*, *ICAM1*, *MMP9*, *NOS3*, and glutathione S-transferase (*GST*) [218-225]; 3) important immunomodulatory genes, like *NFKB*, *IRF1*, *CTLA4*, *STAT4*, and *CD40* [226-232]; and 4) genes encoding receptors of the innate immunity, as *TLR2*, *TLR4*, *TLR9*, TNF receptor superfamily 1A (*TNFRSF1A*), *FCGR2A*, *FCGR3A* and *FCGR3B* [233-238]. Interestingly, an epistatic interaction between the KD-associated *ERAP1* gene and *HLA-B* was proposed to influence BD predisposition in the Spanish population [239]. Nevertheless, studies on well-powered cohorts are required to definitively confirm or discard these associations.

SHARED GENETIC COMPONENT IN VASCULITIS

A large number of the known susceptibility loci described across this chapter are shared amongst different vasculitides (Figure 1), which supports the hypothesis of common molecular pathways influencing the development of autoimmune diseases in general and vasculitides in particular [240]. In this regard, the Immunochip platform is a valuable tool that allows comparison of the genetic landscape between different immune-mediated conditions, as it contains a large panel of SNPs covering most immune genes and in all cases the markers analyzed are the same [241]. In order to obtain genetic insights into the common immunopathological pathways involved in vasculitis development, our group carried out two cross-phenotype meta-analyses of Immunochip data from different forms of vasculitis in collaboration with several consortia [242, 243].

In the first of them, the previously published Immunochip studies of GCA and TAK [16, 71] were combined to evaluate the shared genetic component of large vessel vasculitis (LVV). As expected, no genetic pleiotropy was observed within the HLA, consistent with the fact that GCA and TAK are archetypal HLA class II and class I diseases, respectively. However, a significant genetic correlation was detected outside the HLA region, with *IL12B* representing the strongest shared susceptibility factor for both forms of LVV. This common association is in agreement with the key role proposed for Th1 and Th17 cells in the granuloma formation of LVV, as its encoded protein is the P40 subunit of both IL-12 and IL-23 (involved in Th1 and Th17 cell differentiation, respectively) [244]. Other genes that showed suggestive signals of common association were *NOS2A*, *ERAP1*, *REL* and *PRKQC* [242].

The second inter disease analysis was aimed at deciphering the shared genetic component of all forms of vasculitis. Hence, Immunochip data from GCA, TAK, AAV, and IgAV/HSP were combined and meta-analyzed. The pooled cohort included a total of 2,465 patients diagnosed with any of these four types of vasculitis and 4,632 unaffected controls. Interestingly, a common signal was identified within the lysine demethylase 4C (*KDM4C*) gene, which encodes a histone demethylase involved in epigenetic mechanisms. The shared association was confirmed in an additional cohort that included a subset of BD patients [243].

Figure 1. Shared genetic risk factors in vasculitides.

Despite the recent advances in the identification of the risk factors underlying vasculitides predisposition, there is still a long road ahead before completing the big picture of their genetic landscape.

In most studies, the limited statistical power and the lack of replication in independent cohorts have made difficult the identification of consistent genetic association signals. However, the establishment of big consortia has represented an important step forward that has facilitated the collection of cohorts large enough to perform adequately powered studies. These international collaborative efforts will definitively help to identify novel risk factors and to confirm previously reported genetic associations.

The use of high throughput genotyping has been also of great help, and data mining of the generated large-scale genetic data is producing valuable insights into the specific and common immunopathological pathways that lead to the development of the different forms of vasculitis.

Chapter 200

NOMENCLATURE AND PATHOLOGIC FEATURES OF VASCULITIDES

ABSTRACT

The goal of this chapter is to establish a general framework for categorizing vasculitis, which also serves as a framework for diagnosing vasculitis. The basis for the names and definitions used in this chapter is the 2012 Chapel Hill consensus conference nomenclature system for vasculitides. The major subdivisions are large vessel vasculitis, medium vessel vasculitis, small vessel vasculitis, variable vessel vasculitis, single-organ vasculitis, vasculitis associated with systemic disease, and vasculitis associated with a probable etiology. Although the names of the first four categories imply that vessel diameter is a defining feature of many forms of vasculitis, the different functional and structural characteristic of vessels are more important than the diameter of the vessel in determining their involvement in different forms of vasculitis, as well as the nature of the pathogenic events that are inducing the inflammation. Vasculitides that will be defined in this chapter include Takayasu arteritis, giant cell arteritis, polyarteritis nodosa, Kawasaki disease, microscopic polyangiitis, granulomatosis with polyangiitis (Wegener), eosinophilic granulomatosis with polyangiitis (Churg-Strauss), anti-glomerular basement membrane disease, cryoglobulinemic vasculitis, IgA vasculitis (Henoch-Schönlein), hypo-complementemic urticarial vasculitis (anti-C1q vasculitis), Behçet disease and Cogan syndrome. Many factors must be taken into consideration to make an accurate and precise clinical diagnosis of vasculitis. These include the type of vessels affected, as for example arteries versus venules; the histopathologic features of the inflammatory process such as leukocytoclastic inflammation or granulomatous inflammation; the immunopathologic features that may include IgA-dominant deposits or a paucity of

* Corresponding Author's Email: jcj@med.unc.edu.

immunoglobulin in vessel walls; the serologic findings such as cryoglobulins or anti-neutrophil cytoplasmic autoantibodies; any significantly associated systemic diseases such as rheumatoid arthritis or systemic lupus erythematosus; and associated etiologies such as hepatitis C virus infection or propylthiouracil exposure; the organ system distribution such as lung versus brain; accompanying extravascular lesions such as necrotizing granulomatosis or aphthous ulcers; or other possible factors. In a given patient, the goal of the clinician is to make a diagnosis, namely, assign a disease name that specifies the nature of the root disease process in the patient, and correctly assigns the particular form of vascular inflammation to the observed signs and symptoms that comprise the clinical criteria of that disorder, while providing useful predictions about disease outcome and appropriate treatment.

Keywords: nomenclature, pathology, vasculitides, Chapel Hill Consensus Conference 2012, ANCA

INTRODUCTION

Vasculitis is inflammation in vessel walls. The categorization and diagnosis of vasculitis is based on the nature of the inflammatory injury in vessels, including the etiology, pathogenesis, pathologic features and associated organ system dysfunction. The diagnosis of vasculitis is based on signs and symptoms of the disease or diagnostic criteria that allow a conclusion about the nature of the inflammatory injury in vessels, including the etiology, pathogenesis and pathologic features. Criteria that lead to a diagnosis in a specific patient may or may not involve direct microscopic visualization of inflammation or its sequela, such as vascular scarring in a tissue sample. However, to make a diagnosis of vasculitis, a conclusion must be reached that vasculitis with certain characteristic pathologic changes is occurring or has occurred in the patient. Thus, the underlying basis for the diagnosis of all patients with vasculitis is the nature of the pathologic inflammatory process that caused the vasculitis, although this does not mean that the pathologic lesions must be directly visualized histologically to make an actionable diagnosis.

This chapter reviews the pathology of many forms of vasculitis and presents an approach to nomenclature, classification and diagnosis that derives from these pathologic lesions. The 2012 Chapel Hill consensus conference nomenclature system (2012 CHCC) will be emphasized [1], since it modified and extended the 1994 CHCC nomenclature [2]. Disease nomenclature is a system of names used to identify and categorize diseases; and as for all words, each name has a definition.

The primary underlying defining characteristics of vasculitis in a patient are the cause and the nature of the vascular inflammation including the type of inflammation and the vascular distribution of inflammation. A diagnosis that refers only to cause or only to clinical/pathologic phenotype is problematic since 1) One cause can produce more than one pattern of injury, for example myeloperoxidase-specific anti-neutrophil cytoplasmic autoantibodies (MPO-ANCA) causing either microscopic polyangiitis (MPA) or granulomatosis with polyangiitis (GPA); and 2) One type of vasculitis can be induced by multiple causes, for example MPA caused by MPO-ANCA or proteinase 3-specific ANCA (PR3-ANCA). When possible, the definition of a vasculitis should include a reference not only to the nature of the inflammatory vascular injury but also the likeliest cause if known.

For example, the name IgA vasculitis (IgAV) emphasizes that the vasculitis is caused by IgA1-dominant immune deposits in the walls of small vessels. The alternative name, Henoch-Schönlein purpura (HSP) was originally based on a set of clinical manifestations that can be caused by multiple etiologies. Use of the term IgAV emphasizes the need to carefully consider the specific cause of the clinical manifestations. However, in a clinical setting, as with other pathologic features, there may be diagnostic criteria that warrant a confident diagnosis of IgA vasculitis in the absence direct observation of IgA in vessel walls by immunohistology. The conclusion that a patient has IgAV predicts clinically important clinical characteristics that guide prognosis and therapy. In patients with similar initial clinical manifestation of purpura, arthralgia and glomerulonephritis, the prognosis and appropriate treatment is very different depending on whether or not the clinical findings, including laboratory testing and pathologic observations are indicative of IgAV, cryoglobulinemic vasculitis, lupus vasculitis, MPO-ANCA MPA or PR3-ANCA GPA. However, the etiology and precise pathogenesis of some forms of vasculitis remains unknown, for example in Kawasaki disease (KD) and Takayasu arteritis (TAK). In this circumstance, the only defining features are the nature of the vasculitis and associated clinical features with no indication in the name about the cause.

The CHCC 2012 provides names and definitions for many forms of vasculitis, but does not provide specific diagnostic criteria or classification criteria [1]. Specific observations that can practicably be made in a patient for clinical management purposes comprise diagnostic criteria. Specific observations that can be made in a patient for inclusion in a cohort of patients for a clinical trial or other research project comprise classification criteria. Although definitions may remain unchanged, diagnostic criteria and classification criteria evolve over time as modalities for evaluating patients develop, for example in improved imaging methods and more sensitive and specific laboratory tests become available.

A widely used first level of categorization of vasculitides divides vasculitides into large vessel vasculitis (LVV), medium vessel vasculitis (MVV) and small vessel vasculitis (SVV) (Figure 1) (Table 1) [1, 2]. This is somewhat problematic because it implies that the size or diameter of the involved vessel alone is the major defining feature for these categories and the major basis for susceptibility to different forms of vasculitis, however this is definitely not the case. The different functional and structural characteristic of these categories of vessels are more important than the diameter of the vessel in determining their involvement in the different forms of vasculitis. The relative size of vessels is merely a convenient characteristic that facilitates reference to these biologically different types of vessels. Another source of confusion is the fact that there is overlap in the types of vessels that can be involved in different forms of vasculitis. In particular, medium and small arteries can be involved by LVV, MVV and SVV.

LARGE VESSEL VASCULITIS (LVV)

CHCC 2012 [1] defines LVV as vasculitis affecting large arteries more often than other vasculitides, and defines large arteries as the aorta and its major branches. However, the point is made that any size artery may be affected. Importantly, the definition states that LVV affects large vessels “more often than other vasculitides” rather than LVV has more large

vessels affected since in a given patients with LVV, there may be, and often are numerically more involved medium and small vessels than large ones.

Reproduced from reference [1] with permission.

Figure 1. Diagram showing the predominant distribution of vessels affected by large vessel vasculitis, medium vessel vasculitis, and small vessel vasculitis. All categories of vasculitis can affect all types of arteries, but large vessel vasculitis most often affects large arteries. Medium arteries are most often affected by medium vessel vasculitis but large and small arteries may be affected. Small vessel vasculitis preferentially affects venules and capillaries, although arteries and veins may be affected. ANCA (antineutrophil cytoplasmic antibody) associated vasculitis affects a broad spectrum of vessels, whereas immune complex vasculitis usually affects capillaries or venules or both.

For example, a patient with giant cell arteritis may have involvement of the aorta, a carotid artery and several major branches of the carotid artery all of which are considered large arteries; however, many more medium and small arteries extending into the scalp, tongue, orbit and eye also may be involved. Thus, in a given patient with a LVV, there may be numerically more medium and small arteries affected. These same arteries can be affected by SVV, but SVV rarely affects the aorta and its main branches. Large vessel, including the aorta, can also be affected by variable vessel vasculitis (VSV) including Behçet disease (BD) and Cogan syndrome (CS); and by infectious vasculitis (e.g., aortitis caused by tertiary syphilis) and lymphoplasmacytic disease, for example aortitis as a component of IgG4-related disease [3]. Inflammation of large vessels with histopathologic features of Takayasu arteritis (TAK) and GCA may occur as isolated single organ vasculitides (SOV), such as isolated aortitis or isolated GCA along visceral arteries. Whether these represents limited expressions of TAK or GCA, or a distinct form of SOV has not been definitively determined.

In addition to the vascular distribution, LVV is characterized pathologically by a predominance of monocytes, macrophages, sometimes including multinucleated giant cells and lymphocytes even in the acute phase of vascular inflammation [3-5].

Table 1. Names for vasculitides adopted by the 2012 International Chapel Hill Consensus Conference on the Nomenclature of Vasculitides

<i>Large vessel vasculitis (LVV)</i>
Takayasu arteritis (TAK)
Giant cell arteritis (GCA)
<i>Medium vessel vasculitis (MVV)</i>
Polyarteritis nodosa (PAN)
Kawasaki disease (KD)
<i>Small vessel vasculitis (SVV)</i>
Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV)
Microscopic polyangiitis (MPA)
Granulomatosis with polyangiitis (Wegener's) (GPA)
Eosinophilic granulomatosis with polyangiitis (Churg-Strauss) (EGPA)
Immune complex SVV
Anti-glomerular basement membrane (anti-GBM) disease
Cryoglobulinemic vasculitis (CV)
IgA vasculitis (Henoch-Schönlein) (IgAV)
Hypocomplementemic urticarial vasculitis (HUV) (anti-C1q vasculitis)
<i>Variable vessel vasculitis (VVV)</i>
Behçet disease (BD)
Cogan's syndrome (CS)
<i>Single-Organ vasculitis (SOV)</i>
Cutaneous leukocytoclastic angiitis
Cutaneous arteritis
Primary central nervous system vasculitis Isolated aortitis
Others
<i>Vasculitis associated with systemic disease</i>
Lupus vasculitis
Rheumatoid vasculitis
Sarcoid vasculitis
Others
<i>Vasculitis associated with probable etiology</i>
Hepatitis C virus-associated cryoglobulinemic vasculitis
Hepatitis B virus-associated vasculitis
Syphilis-associated aortitis
Drug-associated immune complex vasculitis
Drug-associated ANCA-associated vasculitis
Cancer-associated (paraneoplastic) vasculitis
Others

In addition, overt fibrinoid necrosis of the vessel wall is absent or a minor feature of LVV lesions, whereas in the acute phase of MVV and SVV there often is a predominance of neutrophils and conspicuous fibrinoid necrosis. LVV may have focal areas of medial coagulative necrosis, possible caused by occlusion of vasa vasorum. It is important to realize that within a week or two of the inception of a focus of acute inflammation in MVV and SVV, the inflammation at that site evolves into chronic inflammation with replacement of neutrophils and necrosis by mononuclear leukocytes and scarring that can be indistinguishable pathologically from chronic LVV. However, many forms of MVV and especially SVV have multiple sites of inflammation arising at different times so that there may be at least some diagnostic acute lesion in a tissue specimen even if there are many less specific chronic lesions.

The two major categories of LVV are TAK and GCA. Although on average there are some pathological and clinical features that differ between these two categories of disease, the

most objective difference is that the onset of TAK is primarily before 50 years old while that of GCA is typically after age 50 years. Thus, CHCC 2012 defines Takayasu arteritis (TAK) as arteritis, often granulomatous, predominantly affecting the aorta and/or its major branches with an onset usually in patients younger than 50 [1]. GCA is defined as arteritis, often granulomatous, usually affecting the aorta and/or its major branches, with a predilection for the branches of the carotid and vertebral arteries, often involves the temporal artery, and with onset usually in patients older than 50 and often associated with polymyalgia rheumatica (PMR) [1].

In the past, the term temporal arteritis was used as synonymous with GCA but this is not an acceptable approach because not all GCA involves the temporal arteritis and not all vasculitis affecting the temporal arteries is GCA. For example, the temporal arteries can be affected by polyarteritis nodosa (PAN), MPA, and GPA [6-8].

Active aortitis and arteritis of TAK and GCA is characterized by transmural inflammation with influx of monocytes, macrophages and lymphocytes (predominantly T lymphocytes) [3-5]. Multinucleated giant cells, formed by the fusion of monocytes into syncytial cells, often are identifiable but are not required for a pathologic diagnosis (Figure 2). Weakening and dilation of vessel walls results in aneurysm formation, and scarring and fibrotic intimal thickening result in narrowing of lumens and ischemia in downstream tissues. In arteries with an elastic media, such as the aorta and its initial branches, special stains for elastic fibers demonstrate a moth eaten appearance with irregular zones of lysis of the multi-laminated elastic media. In non-elastic arteries, there is focal fragmentation of the internal elastic lamina at the junction between the media and the intima. Fibrinoid necrosis is uncommon and when present is usually a minor feature of the overall injury. The presence of extensive fibrinoid necrosis should raise the possibility of some form of MVV or SVV [6-8].

MEDIUM VESSEL VASCULITIS (MVV)

CHCC 2012 [1] defines MVV as vasculitis predominantly affecting medium arteries defined as the main visceral arteries and their branches. Any size artery may be affected and inflammatory aneurysms and stenoses are common. In the acute phase, the inflammation typically is accompanied necrosis, which may result of spillage of plasma constituents into the vessel wall and perivascular tissues where the constituent coagulation cascade contacts thrombogenic stimuli, including tissue factor, resulting in the formation of fibrin. This irregular accumulation of fibrin in areas of necrosis is called fibrinoid necrosis and is deeply eosinophilic in hematoxylin and eosin (H&E) stained sections (Figure 3), and red (fuchsinophilic) in Masson trichrome stained sections (Figure 4A).

Within a week or two, foci of fibrinoid necrosis are replaced by collagenous matrix as the site of acute necrosis transforms into chronic scar. The initial infiltrating inflammatory cells are neutrophils, especially in polyarteritis nodosa; and monocytes, especially in Kawasaki disease. As the acute phase of inflammation transforms into the chronic phase of inflammation and sclerosis, macrophages and T lymphocytes become the predominant inflammatory cells.

The two major categories of MVV are PAN and KD. CHCC 2012 [1] defines PAN as necrotizing arteritis of medium or small arteries without glomerulonephritis or vasculitis in

arterioles, capillaries, or venules; and not associated with ANCA or mucocutaneous lymph node syndrome. The absence of ANCA helps distinguish the necrotizing arteritis of PAN from the histopathologically indistinguishable necrotizing arteritis of ANCA-associated vasculitis (AAV) [9, 10]. The absence of mucocutaneous lymph node syndrome distinguishes PAN from the necrotizing arteritis of KD [1]. Further, necrotizing arteritis that is indistinguishable from PAN also can secondarily occur in systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and other systemic autoimmune and autoinflammatory conditions; secondary to infection notably with the hepatitis B virus (HBV); and as a component of variable vessel vasculitis (VVV) in BD and CD; or as a SOV such as cutaneous arteritis.

Figure 2. Multinucleated giant cells in the inflamed media of the aorta (aortitis) in a patient with giant cell arteritis (H&E stain).

Figure 3. (a) (left): Irregular accumulation of eosinophilic fibrin in areas of fibrinoid necrosis with adjacent neutrophil-rich leukocyte infiltration in a medium artery in a patient with polyarteritis nodosa. (b) (right): Renal interlobar artery in a patient with Kawasaki disease with transmural inflammation including intimal arteritis, medial inflammation with dehiscence of medial cells, adventitial inflammation and a small focus of intimal fibrinoid necrosis (arrow).

Figure 4. ANCA associated vasculitis with (a) necrotizing arteritis with extensive fibrinoid necrosis that stains red with a Masson trichrome stain, (b) glomerulonephritis with segmental fibrinoid necrosis (arrow) that is red with the Masson trichrome staining and a cellular crescent overlying the top of the tuft, (c) dermal leukocytoclastic angitis affecting a venule (arrow) with adjacent hemorrhage and leukocyte infiltration with numerous neutrophils and leukocyte nuclear fragmentation (leukocytoclasia), (d) hemorrhagic alveolar capillaritis with neutrophils in the alveolar septa and hemorrhage in the alveolar air spaces.

Thus, a diagnosis of PAN is a diagnosis of exclusion, that is, all other forms of vasculitis that can cause necrotizing arteritis must be excluded before a diagnosis of PAN is appropriate. In a clinical setting, this can be difficult and may require that a patient initially have a generic diagnosis of necrotizing arteries until a more specific diagnosis is warranted.

KD is defined as arteritis associated with the mucocutaneous lymph node syndrome and predominantly affecting medium and small arteries [1]. Coronary arteries are often involved although the aorta and other large arteries may be involved. KD usually occurs in infants and young children, with onset after 5 years old very uncommon. The acute necrotizing arteritis of

KD can resemble the acute lesion of PAN, which is why this disease was once called infantile PAN by some investigators. However, in general, compared to PAN the acute arteritis of KD has more monocytes, less neutrophils, and more vessel wall edema (medial cell dehiscence) and less fibrinoid necrosis (Figure 3B). Coronary arteritis can occur anywhere along the course of coronary arteries in the epicardium and myocardium, but occurs most often in the origin of the coronary arteries adjacent to the aorta. Inflammatory aneurysms form at the sites of inflammation and necrosis, and may induce thrombosis resulting in myocardial infarction, which is the major cause for mortality in KD.

SMALL VESSEL VASCULITIS (SVV)

CHCC 2012 [1] defines SVV as vasculitis predominantly affecting small vessels, defined as small intraparenchymal arteries, arterioles, capillaries and venules. Medium arteries and veins may be affected. As noted already, LVV and MVV also can affect arteries, and MVV can cause acute necrotizing inflammatory lesions in arteries that are indistinguishable from the lesions of SVV necrotizing arteritis. Both MVV and LVV cause necrotizing arteritis with conspicuous fibrinoid necrosis (Figure 3A and 4A). Thus, identifying arteritis does not distinguish between MVV and SVV. Whether or not arterioles are involved also is not an effective means of distinguishing between MVV and SVV because identifying arterioles versus small arteries is problematic. The most workable definition of arterioles is “the smallest branches of arteries.” Definitions of arterioles based on structural features such as layers of muscle cells in the media and absence on internal elastica; do not consistently identify a distinct vessel type.

Thus using arteriolar involvement is not a reliable approach to distinguishing between MVV and SVV. The best approach for identifying a SVV is to identify involvement of venules and capillaries, for example dermal venulitis (Figure 4C), glomerular capillaritis (glomerulonephritis) (Figure 4B) or pulmonary alveolar capillaritis (Figure 4D).

According to CHCC 2012 [1], SVV is further subcategorized on the basis of immunopathologic findings into AAV or immune complex SVV (Table 1) (Figure 1). AAV has few or no deposits of immunoglobulin or complement in affected vessel walls, whereas immune complex SVV has moderate to marked vessel wall deposits of immunoglobulin and/or complement components (Figure 5).

This paucity of immunostaining for immunoglobulins in involved vessels in patients with AAV is the basis for the pathologic term “pauci-immune” to distinguish AAV and glomerulonephritis from immune complex vasculitis and glomerulonephritis.

This subcategorization is warranted in part because there is compelling evidence that the ANCA and the vessel wall immune deposits are not only useful biomarkers for diagnosis but also are prime movers in the pathogenesis of the vascular inflammation [13].

ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

CHCC 2012 [1] defines AAV as necrotizing vasculitis with few or no immune deposits, predominantly affecting small vessels including capillaries, venules, arterioles and small arteries, and association with MPO-ANCA or PR3-ANCA. However, not all patients have ANCA. A prefix should be added to the name indicating the ANCA reactivity, for example PR3-ANCA, MPO-ANCA, or ANCA-negative [1, 15].

Figure 5. (a) Dermal venules with granular vessel wall staining for IgA in a patient with IgA vasculitis (Henoch-Schönlein purpura) (Fluoresceinated anti-IgA stain). (b) Glomerular capillary basement membranes with linear staining for IgG in a patient with anti-GBM disease (Fluoresceinated anti-IgG stain).

AAV are further categorized as MPA, GPA and EGPA [1]. Thus, when adequate information is available, an optimum AAV diagnosis based on CHCC 2012 includes both the ANCA serotype and the clinicopathologic phenotype, such as MPO-ANCA MPA, PR3-ANCA MPA, MPO-ANCA GPA, PR3-ANCA GPA, ANCA-negative GPA, and MPO-ANCA-EGPA. In a clinical setting, the serotype alone predicts some disease characteristics (Figure 6) and outcomes as for example the frequency of recurrence after induction of remission; while the clinicopathologic variant alone also predicts some disease characteristics and outcomes. However, the two together give a more complete picture about the patient and expected treatment [14, 15]. Thus, from a practical perspective, the available information may require that a more generic diagnosis be made initially, as for example MPO-ANCA AAV, and then refined after more thorough evaluation or as clinical manifestations evolve such as the emergence of compelling evidence for GPA rather than MPA.

MPA is defined as necrotizing vasculitis, with few or no immune deposits, predominantly affecting small vessels such as capillaries, venules, and arterioles [1].

Reproduced from [14] with permission.

Abbreviations: No Lung and No ENT (ear, nose and throat involvement): Vasculitis in any organ except the lungs and the ENT system; Lung no ENT: Vasculitis localized in the lungs but not in the ENT system; Lung: Vasculitis localized in the lungs without indicative markers such as nodules or cavities, or histological proof such as granulomas indicative of granulomatous inflammation; Plus Gastrointestinal (GI involvement): Vasculitis localized at any organ plus involvement of the gastrointestinal tract; Plus Skin: Vasculitis localized at any organ plus dermal involvement; Plus Nerves: Vasculitis localized at any organ plus involvement of the nerves; Any Lung: Any type of pulmonary vasculitis such as pulmonary hemorrhage, infiltrates, nodules, cavities, granulomas, or respiratory arrest; ENT, no Lung: Vasculitis localized to the ENT system but not in the lungs; Any ENT: Any type of vasculitic manifestation of the ENT system; Lung with nodules: Vasculitis localized at the lungs with radiographic proof of nodules; Lung plus ENT: Any type of pulmonary vasculitis plus any type of vasculitic manifestation of the ENT system.

Figure 6. Frequency of PR3- and MPO-ANCA specificity correlated with clinical manifestations of AAV disease. Organ groupings are not mutually exclusive.

Necrotizing arteritis involving small and medium arteries may be present (Figure 4A). Necrotizing glomerulonephritis is very common (Figure 4B). Pulmonary capillaritis often occurs (Figure 4D). Granulomatous inflammation is absent.

All of the lesions observed in MPA can occur in patients with GPA and EGPA. Thus, among patients with AAV, a diagnosis of MPA is a diagnosis of exclusion, once GPA and EGPA are ruled out. Of course, in a clinical setting this is never unequivocal, because a patient thought to have MPA may in fact have an occult focus of necrotizing granulomatosis. This may not be a major problem because the presentation at that time may be primarily as MPA, and if the GPA features become overt, the working diagnosis would change to GPA.

The histopathologic lesions of immune complex SVV can be indistinguishable from those of AAV. For example, leukocytoclastic angiitis or vasculitis (LCV) (Figure 4C) in the skin can be caused by any of the systemic variants of AAV including MPA, GPA, and EGPA, as well as, most if not all forms of immune complex SVV, including but not limited to IgAV, cryoglobulinemic vasculitis (CV) and serum sickness.

Light microscopy alone is not sufficient to identify the cause of LCV. Additional data are required, such as serologic findings and tissue immunostaining.

GPA is defined as necrotizing granulomatous inflammation usually involving the upper and lower respiratory tract, and necrotizing vasculitis affecting predominantly small to medium vessels such as capillaries, venules, arterioles, arteries and veins [1]. Necrotizing glomerulonephritis is common. The defining granulomatosis of GPA is a very destructive lesion that in the acute phase resembles an abscess (Figure 7A) more than a typical granuloma. In the acute phase, neutrophils predominate at the sites of granulomatosis, and a few scattered multinucleated giant cells are the only histologic features justifying a designation of granulomatosis.

However, as the lesions evolve, the neutrophils in the central zone of necrosis lyse and are replaced by amorphous necrotic debris, and epithelioid macrophages form palisades that wall of the zone of necrosis in a typical granulomatous pattern (Figure 7B).

EGPA is defined as eosinophil-rich and necrotizing granulomatous inflammation often involving the respiratory tract, and necrotizing vasculitis predominantly affecting small to medium vessels, and associated with asthma and eosinophilia. ANCA is more frequent when glomerulonephritis is present. The asthma that precedes EGPA typically is late onset, and affected patients often have a prodromal phase of eosinophil rich inflammatory disease for example eosinophilic pneumonia or eosinophilic gastroenteritis, prior to the onset of definitive manifestations for vasculitis or glomerulonephritis [15]. Eosinophils are conspicuous at sites of tissue inflammation, including sites of vasculitis (Figure 8).

However, similar prominence of eosinophils can be observed in lesion of MPA and GPA, thus this is not diagnostic in the absence of the asthma and blood eosinophilia.

With sensitive clinical assays, 90% or more of patients with active untreated MPA and GPA are ANCA positive, with PR3-ANCA more frequent in GPA and MPA in Europe and North America [16].

Figure 7. Lung tissue from a patient with granulomatosis with polyangiitis (Wegener's) showing (a) an early lesion with an intense infiltrate of neutrophils on the right and an adjacent accumulation of macrophages including a multinucleated giant cell (arrow), (b) more advanced granulomatosis with an amorphous zone of necrosis on the right and an adjacent zone of palisading epithelioid macrophages (Hematoxylin and eosin [H&E] stain).

Figure 8. Arteritis in a patient with eosinophilic granulomatosis with polyangiitis (Churg-Strauss) showing intimal arteritis with numerous eosinophils in an expanded intima (left), scattered eosinophils in the media, and numerous eosinophils in the adventitia (right) (H&E stain).

However, <50% of patients with EGPA are positive for ANCA, almost always MPO-ANCA [16]. Interestingly, more than 75% of EGPA patients with renal disease are ANCA-positive compared to approximately 25% of EGPA patients with no clinical evidence for kidney disease [17].

Organ limited expressions of AAV occur, for example isolated cutaneous vasculitis, lung capillaritis, upper respiratory tract granulomatosis, or pauci-immune necrotizing and crescentic glomerulonephritis also called renal-limited vasculitis. In some but not all patients, multisystem involvement is identified later. Isolated granulomatosis often is considered a limited form of GPA and isolated vasculitis as a limited form of MPA if the lesions otherwise are identical to those observed in systemic AAV.

IMMUNE COMPLEX SMALL VESSEL VASCULITIS

CHCC 2012 [1] defines immune complex SVV as vasculitis with moderate to marked vessel wall deposits of immunoglobulin and/or complement components predominantly affecting small vessels such as capillaries, venules, arterioles and small arteries; glomerulonephritis is frequent.

Immune complex SVV differs immunopathologically from AAV with respect to the extent of immunoglobulin deposited in vessel walls. This most likely is a reflection of the different etiologies and pathogenic mechanisms. Immune complex vasculitis appears to result from initial extensive localization of immune complexes in vessel walls followed by complement activation and mediation of inflammation. The immunoglobulin is diffusely distributed in the walls of affected small vessels. In contrast, AAV appears to be mediated by more direct interaction of ANCA with neutrophils and monocytes resulting in activation that

in turn releases factors that activate the alternative complement pathway, which amplifies the inflammation to cause the severe necrotizing lesions of AAV [13].

There are many forms of immune complex SVV caused by immune complexes of different compositions. The antigens in pathogenic immune complexes can be derived from heterologous sources such as infectious pathogens or drugs, or from endogenous sources such as autoantigens. CHCC 2012 only defines several of these many variants: anti-glomerular basement membrane (anti-GBM) disease, CV, IgAV, and hypocomplementemic urticarial vasculitis (HUV) (anti-C1q vasculitis).

Anti-GBM disease is defined as vasculitis affecting glomerular capillaries, pulmonary capillaries, or both, with basement membrane deposition of anti-basement membrane autoantibodies. Lung involvement causes pulmonary hemorrhage, and renal involvement causes glomerulonephritis with necrosis and crescents.

From an immunopathologic perspective, anti-GBM disease is somewhat distinct from many other forms of immune complex vasculitis and glomerulonephritis because immunostaining of involved capillaries shows linear staining rather than granular staining (Figure 5B). This is because the target autoantigen is a diffusely distributed constituent component of the glomerular and alveolar capillary basement membranes, type IV collagen. Thus, immune complexes containing anti-GBM antibodies and type IV collagen form in situ diffusely along these basement membranes resulting in the linear staining. By contrast, other types of immune complexes gather stochastically and irregularly within vessels walls producing the granular pattern of immunostaining. The inflammatory vascular injury of anti-GBM disease affects glomerular capillaries, pulmonary capillaries, or both, with focal rupture of capillary walls and hemorrhage into the urinary space or alveolar air spaces.

By routine light microscopy, neutrophils often are not conspicuous at sites of necrosis, probably because they are destroyed in the process of activation and necrosis. However, in some lung specimens, more overt pulmonary capillaritis with influx of neutrophils is observed [18]. Approximately a third of patients with anti-GBM disease also have ANCA, usually MPO-ANCA [19]. They have an initial renal outcome more like anti-GBM disease than AAV with a higher rate of progression to end stage [19]. Renal biopsy specimens from patients with concurrent anti-GBM and ANCA may reveal necrotizing arteritis as well as glomerulonephritis.

Cryoglobulinemic vasculitis (CV) is defined as vasculitis with cryoglobulin immune deposits affecting small vessels (predominantly capillaries, venules, or arterioles) and associated with cryoglobulins in serum [1]. Skin, glomeruli and peripheral nerves are often involved. Localization of cryoglobulins in vessel walls incites inflammation (vasculitis) by complement activation [20, 21]. Monoclonal cryoglobulins (type I) are not as effective at activating inflammatory mediator systems as are mixed cryoglobulins (types II and III), which are immune complexes composed of anti-antibodies or rheumatoid factors (RF) bound to target antibodies. An important cause for cryoglobulinemia is hepatitis C virus (HCV) infection [21]. Acute CV affecting venules, arterioles and small arteries typically has neutrophilic infiltration with leukocytoclasia (Figure 9). The inflammation may be accompanied by luminal or vessel wall deposits of PAS-positive hyaline material composed of coagula of cryoglobulins (Figure 9). Cryoglobulinemic glomerulonephritis occurs as a renal limited process and as a component of systemic CV. Cryoglobulinemic glomerulonephritis usually has a membranoproliferative pattern but may have other patterns

of proliferative glomerulonephritis. A frequent finding is hyaline material in glomerular capillary lumens (“hyaline thrombi”) that are coagula of cryoglobulins.

Although glomerulonephritis is a frequent component of many forms of immune complex SVV, the glomerular lesions, including immunopathologic features, are very helpful in distinguishing among them, for example, CV with membranoproliferative lesions and IgG/IgM deposits, IgAV with IgA-dominant deposits, anti-GBM disease with necrosis and linear IgG, and AAV vasculitis with necrosis and a paucity of immunoglobulin deposits.

IgAV is defined as vasculitis, with IgA1-dominant immune deposits, predominantly affecting small vessels such as capillaries, venules, and arterioles (Figure 5A) [1]. IgAV often involves skin and gastrointestinal tract, and frequently causes arthritis. Glomerulonephritis indistinguishable from IgA nephropathy may occur. The shift in terminology to IgA vasculitis is prompted in part by mounting evidence that abnormally reduced glycosylation of the O-linked glycans in the hinge region of IgA1 molecules play a pivotal pathogenic role in IgA vasculitis and IgA nephropathy [22, 23].

In patients with these diseases, serum IgA1 has reduced terminal galactosylation and sialylation, resulting in increased exposure of N-acetylgalactosamine at the ends of the hinge region glycans. There also is evidence that patients have autoantibodies that recognize these abnormally glycosylated IgA1 hinge regions, which could result in immune complex formation. In addition to forming pathogenic immune complexes, abnormal glycosylation of the glycans in the hinge region of IgA1 molecules could play a pathogenic role through a variety of other mechanisms, such as reduced clearance from the circulation because of lack of receptor engagement by the abnormal IgA, increased aggregation of IgA in the circulation resulting in mesangial trapping, and increased affinity of the abnormal IgA for mesangial matrix.

Figure 9. Inflammation of a small interlobular renal artery in a patient with cryoglobulinemic vasculitis. The arrow points to some hyaline material in the lumen that may be aggregated cryoglobulins. Some of the vessel wall leukocytes are undergoing leukocytoclasia (PAS stain).

Purpura hematuria and proteinuria are frequent clinical manifestations of IgA vasculitis that also are shared by other forms of SVV, including AAV and cryoglobulinemic vasculitis [24]. Demographic, clinical, laboratory and pathology observations all help resolve the differential diagnosis. For example, IgAV is most frequent in children, especially children under 10 years old, whereas AAV and CV are more common in older patients. However, all can occur at any age. Useful disease markers include immunohistologic findings such as IgA1 deposits, cryoglobulin deposits, and a paucity of deposits; and serologic tests under glycosylated IgA1, RF and ANCA.

The glomerular lesions in the kidney are indistinguishable from those of IgA nephropathy although necrosis, crescents and capillary wall deposits are somewhat more frequent in IgA vasculitis patients who undergo renal biopsy. In addition to the glomeruli, IgA1-dominant immune deposits occur in renal arterioles and peritubular capillaries in <20% of patients. IgA1-dominant immune deposits also can be identified in small vessels of the skin and gut; however, this is not of value in differentiating IgA vasculitis from IgA nephropathy because many IgA nephropathy patients also have IgA in dermal venules.

HUV is accompanied by urticaria and hypocomplementemia affects small vessels such as capillaries, venules, and arterioles, and is associated with anti-C1q antibodies [1]; glomerulonephritis, arthritis, obstructive pulmonary disease, and ocular inflammation are common.

HUV is characterized by recurrent episodes of urticaria with underlying leukocytoclastic vasculitis that causes hemorrhage into the lesions [24]. Skin manifestations include painful, tender, burning or pruritic lesions that persist for greater than 24 hours, often with central or diffuse areas of hemorrhage. HUV can be isolated or associated with autoimmune diseases (including lupus), infections, drug reactions, or neoplasms. Proteinuria and hematuria occur in 20-30% of patients and the underlying glomerular lesion usually has a membranoproliferative pattern, but other proliferative and focal necrotizing lesions may occur. Glomeruli and dermal vessels have granular deposits of IgG, IgA, IgM, C3 and C1q, which resembles the “full house” immunostaining seen in SLE.

IgG autoantibodies to the collagen-like region of C1q (anti-C1q) are usually present and may play a role in pathogenesis [25]. The hypocomplementemia appears to be secondary to classical pathway activation with reduced C1, C2, C4, and C3. The marked localized edema (urticarial) may be a manifestation of enhanced complement mediated vascular permeability resulting from an effect of anti-C1q antibodies on complement activation.

VARIABLE VESSEL VASCULITIS

VVV is a category of vasculitis that was not included in the CHCC 1994 nomenclature system [2]. The CHCC 2012 defines VVV as vasculitis with can affect vessels of any size (small, medium, and large) and type (arteries, veins, and capillaries). Two protean vasculitides are included, Behçet disease (BD) and Cogan’s syndrome (CS) [1]. Although these disease are rare and vasculitis caused by them is even rarer, they were included for completeness and so that they will be considered in the differential diagnosis of patients with vasculitis.

BD is clinically characterized by recurrent oral and/or genital aphthous ulcers accompanied by cutaneous, ocular, articular, gastrointestinal, and central nervous system (CNS) inflammatory lesions. Small vessel vasculitis, thromboangiitis, thrombosis, arteritis and arterial aneurysms may occur. The associated vasculitis can involve both arteries and veins of all sizes for example the aorta and large arteries to small mucosal and cutaneous veins, venules, arterioles and arteries (Figure 10) [24, 27-29]. The aorta and other large arteries such as the pulmonary arteries may demonstrate transmural neutrophil-rich inflammation resulting in aneurysm formation, and small vessels have leukocytoclastic angiitis. Aortitis and arteritis can result in aneurysm formation, vascular stenoses and occlusions. Arterial complications are less common than venous lesions, which include phlebitis and thrombosis. A variant called ‘vasculo-Beçet disease’ has prominent vascular complications including vasculitis, thrombosis, stenoses, occlusions, and aneurysms.

CS is clinically characterized by ocular inflammatory lesions, including interstitial keratitis, uveitis, and episcleritis, and inner ear disease, including sensorineural hearing loss and vestibular dysfunction [30-32]. The associated vasculitis which occurs in approximately 15% of affected patients, includes arteritis of small, medium or large arteries; aortitis, aortic aneurysms, and aortic and mitral valvulitis [1]. Involved vessels can have transmural infiltration of neutrophils in the acute phase.

Figure 10. Leukocytoclastic angiitis affecting a small subcutaneous artery in a patient with Behçet's disease (H&E stain).

The differential diagnosis of a patient with CS includes GPA, EGPA, RV, and relapsing polychondritis, all of which may be complicated by inflammatory eye disease and, less commonly, sensorineural hearing loss [30].

SINGLE-ORGAN VASCULITIS

CHCC 2012 defines SOV as vasculitis in arteries or veins of any size in a single organ that has no features that indicate that it is a limited expression of a systemic vasculitis [1]. The

involved organ and vessel type should be included in the name, for example cutaneous small vessel vasculitis, testicular arteritis, and CNS vasculitis. Vasculitis distribution may be unifocal, multifocal or diffuse within an organ. Some patients originally diagnosed with SOV will develop additional disease manifestations that warrant redefining the case as one of the systemic vasculitides, as for example cutaneous arteritis later developing into systemic polyarteritis nodosa. A diagnosis of SOV always requires careful exclusion of systemic vasculitis.

Many forms of SOV have been reported, for example cutaneous LCV [24], cutaneous arteritis or cutaneous polyarteritis [24, 33, 34], primary angiitis of the CNS (PACNS) [35] or the equivalent term primary CNS vasculitis (PCNSV) [36]; isolated aortitis, and others [37]. The histopathologic pattern of injury can resemble any of the recognized forms of systemic vasculitis, although necrotizing arteries and granulomatous arteritis are most frequent.

Figure 11. Primary central nervous system vasculitis (CNS single organ vasculitis) affecting a small intracerebral artery with granulomatous inflammation resulting in perivascular hemorrhage (H and E stain).

An extended period of surveillance is recommended to substantiate the accuracy of the diagnosis of SOV and that excision of the affected site provides a cure [37]. Moreover, CHCC 2012 recommends that the term SOV not be used for organ-limited expressions of vasculitides that usually have multisystem involvement, for example GPA confined to the lungs also known as lung-limited GPA; or ANCA-positive pauci-immune necrotizing glomerulonephritis without systemic vasculitis also known as renal-limited-AAV.

VASCULITIS ASSOCIATED WITH SYSTEMIC DISEASE

CHCC 2012 acknowledges that vasculitis can be associated with different systemic diseases, which may be causing the vasculitis [1]. Therefore the name or diagnosis should include a prefix term specifying the systemic disease such as rheumatoid vasculitis, lupus

vasculitis and sarcoid vasculitis (Figure 12). There is a subjective distinction between vasculitis secondary to a systemic inflammatory disease and vasculitis that is characteristic of a systemic inflammatory disease. In some instances, it may be a relatively infrequent feature of a systemic disease as for example vasculitis in rheumatoid arthritis, or a frequent feature and therefore characteristic component of the systemic disease, such as in GPA; however in CS, vasculitis falls into a gray zone. The important concept is that whenever a vasculitis is identified, the possibility of vasculitis secondary to a systemic disease should be considered.

Figure 12. Necrotizing arteritis in the perirenal adipose tissue of a patient with systemic lupus erythematosus showing focal fibrinoid necrosis and leukocyte infiltration (H and E stain).

VASCULITIS ASSOCIATED WITH PROBABLE ETIOLOGY

CHCC 2012 acknowledges that vasculitis may be associated with a probable specific etiology [1]. In this case, the name or diagnosis should have a prefix term specifying the association, for example hydralazine-associated microscopic polyangiitis, HBV-associated vasculitis and HCV-associated CV, minocycline-associated vasculitis, and paraneoplastic vasculitis.

The likelihood that an association with a probable etiology is because of a causal relationship depends on the credibility of the supporting data. Some etiologic relationships are reflected in the names of major categories and others designate categorical subsets. For example, propylthiouracil-associated MPO-ANCA and HCV-associated CV are designations that each refer to two different etiologies that act in sequence to cause vasculitis, highlighting the importance of using diagnostic terms that provide information about likely or definite causes of vasculitis in a given patient.

Emerging data from genomic, proteomic and metabolomic studies are demonstrating previously unrecognized probable etiologies and pathogenic mechanisms [38]. Monogenic mutations have been discovered associated with various patterns of vasculitis. For example,

Deficiency of Adenosine deaminase 2 (DADA2) resulting from mutations in the CECR1 gene can cause a necrotizing vasculopathy that resembles PAN pathologically and clinically. However, DADA differs clinically from typical PAN because the onset usually is in childhood [39].

CONCLUSION

Many factors must be taken into consideration in rendering an accurate and precise clinical diagnosis of vasculitis in a given patient, such as the clinical signs and symptoms, results of laboratory tests, and the observed histopathology of involved organ tissue. Important parameters include the types of vessels affected, as for example arteries or venules; the pathologic features of the inflammatory process such as leukocytoclastic inflammation versus granulomatous inflammation; immunopathologic features such as IgA-dominant deposits or paucity of immunoglobulin in vessel walls; serologic findings such as cryoglobulins or ANCA; associated systemic disease such as RA or SLE; proximate etiologies such as HCV and propylthiouracil; the distribution of lesions to affected organ systems such as the lungs versus the gut; and any accompanying extravascular lesions such as necrotizing granulomatosis or aphthous ulcers, and other factors.

Chapter 201

CLASSIFICATION OF PEDIATRIC VASCULITIDES

***Seza Ozen**, MD**

Department of Pediatric Rheumatology,
Hacettepe University School of Medicine, Sıhhiye/Ankara, Turkey

ABSTRACT

The primary systemic vasculitides in childhood are quite uncommon with the exception of Ig A vasculitis (Henoch-Schönlein purpura) and Kawasaki disease. Although children and adults share many characteristics in vasculitis, they also differ in certain aspects of different vasculitic diseases. The criteria of the 2012 Chapel Hill Consensus nomenclature and the validated Ankara 2008 classification for childhood vasculitides can be applied to pediatric practice. Advances in the understanding and diagnosis of childhood primary systemic vasculitis will continue to shape classification criteria in the future.

Keywords: pediatric, vasculitis, classification

INTRODUCTION

Vasculitis is characterized by the inflammation of the blood vessels leading to vascular stenosis, occlusion, aneurysm, or rupture [1]. The vasculitides have specific vessel involvements, specific organ system choices and sometimes age selections. In fact, the types of vasculitis and their course differ in childhood. With an overall estimated incidence of childhood vasculitis of about 50 cases per 100,000 children per year [2], the most frequent vasculitic disorders are IgA Vasculitis (Henoch Schonlein purpura) (IgAV (HSP)) and Kawasaki disease (KD) [2]. The prevalence of childhood HSP and KD range from 13.5/100,000 for IgAV (HSP) [3, 4], and 135 to 200/100,000 IgAV/for KD in Japan to 9 to 17/100,000 in Caucasians [5]. This compares with the lower prevalence of adult vasculitides

* Corresponding Author's Email: sezaozen@gmail.com; Tel: +90 3123051863; Fax: +90 312312398.

wherein the estimated annual incidence for IgAV (HSP) is 0.8 to 1.8/100 000 [6], and around 10/million total population for both granulomatosis with polyangiitis (GPA) (Wegener granulomatosis) and microscopic polyangiitis (MPA) [7, 8].

The 2012 revised definitions of the Chapel Hill consensus conference vastly improved the understanding of the vasculitides [9]. The new nomenclature is reviewed elsewhere in this volume, however neither are they intended to be classification or diagnostic criteria.

Many vasculitides affect both children and adults. However, some, like KD, occur exclusively in childhood, while others such as temporal arteritis rarely if ever occur in childhood. Children and adults also differ in the etiology, relative frequency of some clinical manifestations, and prognostic characteristics of different vasculitides [9, 10]. This may be due to immune system differences between adults and children. With aging, certain changes occur in the immune system. With aging, there is progressive thymic involution that decreases the number of naïve and regulatory T-cells. There is continuous reshaping of the immune repertoire by persistent antigenic challenges as well as, reduced production of naïve B cells and dysregulation of toll-like receptors that have major roles in innate immunity [11]. These changes may have direct linkages with different autoimmune disease susceptibility.

Disease classification systems are based on arbitrary combinations of different disease characteristics with the purpose of differentiation of closely related syndromes [12]. The primary objective of classification criteria is to define homogenous patient populations mainly for research purposes and epidemiological data; not to diagnose disease in individuals [13]. A diagnosis is made by considering all clinical features of the patient, not only the classification criteria [14]. However, classification criteria are used for diagnosis in practice, albeit with a low sensitivity [14]. In 1990, the American College of Rheumatology (ACR) proposed classification criteria for adult patients with vasculitides [16-20]. However, it had a number of shortcomings. For example, ACR criteria excluded MPA as a disease category, and there was no reference to antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitides (AAV) or KD [16-20]. In as much as the ACR criteria were not validated in children, they were not suitable for childhood vasculitis. With this background, in 2005, the vasculitis-working group of the Pediatric Rheumatology European Society (PRES) proposed preliminary classification criteria for some of the commonest childhood vasculitides: HSP/IgAV, childhood polyarteritis nodosa (PAN), GPA, childhood Takayasu arteritis (TA) and KD [21]. These criteria were validated and took the final form at the 2008 Ankara Consensus Conference with support from the European League Against Rheumatism (EULAR) and the Pediatric Rheumatology International Trials Organization (PRINTO) [22, 23]. In a recent study [24], the Ankara 2008 criteria performed better in a large cohort of North American GPA patients.

IGA VASCULITIS / HENOC-SCHÖNLEIN PURPURA

HSP/IgAV is the most common form of childhood vasculitis with an incidence of at least 135 per 1 million children [3, 4]. About 90% of IgAV/HSP patients are younger than 10 years of age [25]. The disease is less severe in children than in adults [26]. To fulfill ACR classification criteria for HSP/IgAV, two of the following are required: age < 20 years, palpable purpura, abdominal pain, and vessel wall granulocytes on biopsy [17].

During the revision process for children, the major change was to make palpable purpura a mandatory criterion [23]. The biopsy criterion was also revised as presence of IgA deposition in any biopsy to increase the specificity of the criteria in children. In addition, it is important to define IgA deposits as “predominant” to differentiate HSP/IgAV from other diseases with IgA deposits [22-24].

It was agreed to use the United Nations/UNICEF definition of a “child” as 18 years or less [27]. Thus, the age criterion in IgAV/HSP was deleted [21]. As the joint involvement is more common in children, it was added to the group of criteria [23]. Renal involvement is the main because of late morbidity and mortality in pediatric IgAV/HSP patients and approximately 40% of children with IgAV/HSP develop nephritis within six weeks of presentation [28]. Renal involvement was also considered as a new criterion to underline its importance in long-term prognosis [23].

In its final form, for IgAV/HSP classification, the Ankara 2008 criteria required the presence of palpable purpura with lower limb predominance plus one of the following four features: diffuse abdominal pain, any biopsy showing predominant IgA deposition, arthritis or arthralgia, and renal involvement (any hematuria and/or proteinuria). If purpura has an atypical distribution, the demonstration of IgA deposits in a biopsy is required [23]. The sensitivity and specificity of these criteria were found as 100% and 87% respectively in children [23].

KAWASAKI DISEASE

KD is an acute, self-limited systemic vasculitis of medium- and small-sized vessels predominantly occurring in children aged 6 months to 5 years [29]. It is the second most common childhood vasculitis and the leading cause of acquired heart disease in children in developed countries [30]. The distribution is worldwide. However, among children younger than 5 years of age, the incidence in Japan (135 to 200 per 100,000) is 10 to 15 times greater than the Caucasian incidence (9 to 17 per 100,000) [5].

KD classification was based on either Japanese or American classification criteria [31, 32]. The Japanese classification criteria for KD requires the presence of five of the following six features: characteristic fever, bilateral conjunctivitis, changes in lips and oral cavity, polymorphous exanthema, changes of peripheral extremities, and cervical lymphadenopathy [32]. The American classification required fever plus four of the remaining five criteria [31].

The major complication of KD is damage to coronary arteries; and while 25% of untreated KD patients suffer from coronary artery aneurysm, this decreases to 4% with proper treatment [33]. In the aforementioned 2006 criteria, it was agreed that a child with typical echocardiographic changes could be classified as KD without fulfilling four of the remaining criteria [21]. The second modification was the addition of perianal desquamation to the criterion describing the changes in extremities [21]. After these modifications, the classification criteria for KD included fever persisting for at least five days (mandatory criterion) plus four of five additional features: changes in the peripheral extremities or perianal area, polymorphous exanthema, bilateral conjunctival injection, changes of lips and oral cavity and/or injection of oral and pharyngeal mucosa, and cervical lymphadenopathy. In the case of fever and coronary artery disease detected by echocardiography, fever than four of

the remaining five criteria are enough to classify a patient as having KD [21]. The American Heart Association recently published suggestions for the diagnosis and management of KD [33].

POLYARTERITIS NODOSA

PAN is a necrotizing vasculitis characterized by aneurysmal nodules along the walls of predominantly medium-sized arteries and multi-organ involvement that affects individuals of all ages [30]. The estimated annual incidence is 2 to 9/million in adults in Europe and the United States [34]. The epidemiologic data are scarce in childhood. However, it is the third most common vasculitis after HSP and KD in children [10, 35].

The ACR requires at least three of the following 10 criteria for the diagnosis of PAN: granulocytic or mixed leukocytic infiltrates in a biopsy of an arterial wall, arteriographic abnormalities, livedo reticularis, myalgia, diastolic blood pressure >90 mmHg, mono or polyneuropathy, elevated blood urea nitrogen or creatinine, testicular pain/tenderness, hepatitis B reactants, and weight loss >4 kg [19].

Modified forms of ACR criteria were being used for PAN classification in childhood [36, 37], however, they were found insufficient, and so, all criteria were revised again.

As hepatitis B serology positivity is unusual in childhood PAN probably due to the vaccination protocols [10], this criterion was removed. Furthermore, according to the 2012 Chapel Hill nomenclature, if the vasculitis is related to hepatitis B infection, it should be classified under “vasculitis associated with probable etiology” [9]. Monogenic diseases may mimic common vasculitic disorders such that deficiency of adenosine deaminase2 mimics PAN with similar histopathological features [38].

The childhood PAN criteria designates the typical histopathology or angiographic abnormalities as a mandatory criterion [23]. In the final validation, the criteria for the signs and symptoms of vasculitis in specific organ systems and testicular pain and tenderness were removed [23]. With all these modifications, the criteria had a sensitivity of 89.6% and a specificity of 99.6% [23].

The Ankara 2008 classification for childhood PAN requires histologic evidence of necrotizing vasculitis in medium- or small-sized arteries or angiographic abnormalities (conventional angiography if magnetic resonance angiography is negative) as a mandatory criterion, plus one of the following five: skin involvement, myalgia or muscle tenderness, hypertension, peripheral neuropathy, and renal involvement [23]. Renal involvement is specified as involvement of medium to small size arteries excluding glomeruli.

CUTANEOUS PAN

CPAN is a form of PAN affecting small- and medium-sized vessels limited to the skin [39]. It constitutes a large group in pediatric practice. In an international survey of childhood vasculitis, approximately one-third of the children with PAN were categorized as CPAN [10]. Although there are no formal classification criteria for CPAN, in 2005, it was defined as cutaneous polyarteritis characterized by the presence of subcutaneous nodular, painful, non-purpuric lesions with or without livedo reticularis, and with no systemic involvement (except

for myalgia, arthralgia, and non-erosive arthritis) [22]. The other defined characteristic features were skin biopsy demonstrating necrotizing non-granulomatous vasculitis, negative tests for ANCA and association with evidence of streptococcal infection [22].

MICROSCOPIC POLYANGIITIS

MPA is a pauci-immune necrotizing small vessel vasculitis. Necrotizing glomerulonephritis occurs in most of the patients with MPA [40]. There are no specific classification criteria for MPA. However, it is described in the 2012 Chapel Hill Consensus Conference (CHCC) [9].

GRANULOMATOSIS WITH POLYANGIITIS (GPA) (WEGENER GRANULOMATOSIS)

GPA is a necrotizing ANCA-associated vasculitis affecting small- to medium-sized vessels [40]. AAV are rare in childhood with an incidence of 0.24/100,000 children annually with GPA as the most frequently diagnosed form [41].

For classification of GPA, the ACR criteria require two of the following four features: nasal-oral inflammation, abnormal chest X ray, abnormal urinalysis, and granulomatous inflammation on biopsy [20].

Approximately 90% of GPA patients are ANCA (mostly classical ANCA) positive [42]. So, any ANCA positivity was added as a new criterion. Most features of GPA are similar in children and adults. However, subglottic stenosis has been reported to be more common in pediatric patients [43, 44]. Based on these data, the presence of subglottic, tracheal, or endobronchial stenosis was added to the group of criteria [23]. Another minor modification was the addition of chest computed tomography (CT) scan results to the definitions based on radiological imaging [23].

According to the final classification, childhood GPA requires at least three of the following six criteria: granulomatous inflammation on biopsy, upper airway involvement, laryngo-trachea-bronchial stenosis, pulmonary involvement (chest radiograph or CT), any ANCA positivity, and renal involvement [23]. It had a sensitivity and specificity of 93.3% and 89.2% respectively, in the validation cohort [23]. In a study on 100 children with GPA, the Ankara 2008 criteria was significantly more sensitive than the ACR 1990 criteria in classifying these patients [24].

TAKAYASU ARTERITIS

TA is a granulomatous large vessel vasculitis involving the aorta and its main branches leading to stenosis and aneurysms [40]. The mean prevalence of TA was 4.7/million in adults [45]; however, pediatric incidence data for TA are not available. It is predominantly the disease of the third decade, but it can occur in children, as well [46]. In fact, 20% of all TA

patients are younger than 19 years of age at disease onset [47] and it has been suggested that age at onset younger than 15 years was associated with a probability of delay in diagnosis [48]. Thus, it is important for pediatricians to suspect and classify children with TA.

The ACR criteria for TA requires the presence of three of the following six criteria: age < 40 years, claudication of the extremities, decreased brachial pulse, and blood pressure difference >10 mmHg between arms, bruit over subclavian arteries or aorta, and arteriographic abnormalities [18].

During the process of revising these criteria for children, the age criterion was deleted and the “angiographic abnormalities” was made a mandatory criterion and modified with imaging modalities such as CT and magnetic resonance imaging (MRI) [23]. Hypertension may be the only symptom in children with TA at presentation, so it was included as a new criterion [21]. The increased acute phase reactants were also included in the criteria as this was an important finding before the onset of complications and could help with the differential diagnosis. With all these modifications, the criteria had a sensitivity of 100% and a specificity of 99% in children [23].

The final classification criteria for childhood TA are angiographic abnormalities of the aorta and its main branches and pulmonary arteries showing aneurysm/dilatation (mandatory criterion) plus one of the five as follows: pulse deficit or claudication, four-limb blood pressure discrepancy, bruits, hypertension, and elevation of acute phase reactants [23].

Finally yet importantly, a group of pediatricians has suggested new classification criteria for childhood Behçet diseases based on a large cohort of cases [49].

CONCLUSION

Primary systemic vasculitides are relatively uncommon in children as compared to adults. However, certain vasculitides such as KD do occur almost exclusively in childhood. Although children and adults may share many common characteristics in vasculitis, they differ in certain aspects such as the etiology, the frequency of some clinical manifestations, and prognosis. As most of the pediatric vasculitides are rare diseases, collaborative multicenter studies are needed to improve these criteria contemporaneously with advances in the diagnostic approach and improved etiopathogenic understanding of these disorders. The pediatric community is also awaiting the classification task led by the adult rheumatologists, which will surely affect our practice as well.

Chapter 202

DETECTION TECHNIQUES AND CLINICAL RELEVANCE OF ANCA TESTING

ABSTRACT

Antineutrophil cytoplasmic antibodies (ANCA) testing is an established diagnostic tool in the necrotizing small vessel vasculitis and their presence define ANCA-associated vasculitides (AAV) including granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic GPA (EGPA). These autoantibodies are also detected in a wide range of inflammatory and infectious diseases leading to a critical reappraisal in the diagnostic significance. The diagnostic utility of ANCA depends on the type of assay performed and the clinical setting. Methods of ANCA detection have been standardized in large multicenter studies. Classically, laboratories screen for ANCA by indirect immunofluorescence (IIF) on ethanol-fixed neutrophils, and positive IIF samples are further analyzed for antibodies to proteinase 3 (PR3) or myeloperoxidase (MPO) by immunoassay. Such diagnostic algorithm is based on an international consensus statement on testing and reporting of ANCA published in 1999. Novel methods for PR3- and MPO-ANCA detection have been developed to improve the performance of traditional ANCA-specific assays and new high quality immunoassays have been shown to have superior diagnostic performance compared to IFT. The 2017 revised consensus recommendations on ANCA testing state that high quality antigen-specific immunoassays are the preferred screening methodology for the diagnosis of ANCA-associated vasculitis. ANCA subtype (PR3-ANCA and MPO-ANCA) are associated with different epidemiological, genetic and clinical features. The remaining challenges in routine clinical practice include the methodological aspects of test performance by antigen-specific immunoassays, the application of testing in clinical settings with low pretest probability of vasculitis, and the value of serial testing in the prediction of disease relapse.

INTRODUCTION

In 1982, Davies and colleagues [2] discovered the association of the antineutrophil antibody in segmental necrotizing glomerulonephritis, and three years later, Van der Woude and coworkers [3] characterized their presence as a diagnostic tool and marker of disease in Wegener's granulomatosis. The spectrum of diseases associated with antineutrophil cytoplasmic antibodies (ANCA) has since increased. Two ANCA are highly associated markers for ANCA-associated vasculitides (AAV), the latter of which includes granulomatosis with polyangiitis (GPA, [Wegener's]), microscopic polyangiitis (MPA), eosinophil granulomatosis with polyangiitis (EGPA), and primary pauci-immune crescentic glomerulonephritis, namely C-ANCA synonymous with cytoplasmic fluorescence and specificity for proteinase 3 (PR3-ANCA) and P-ANCA with perinuclear fluorescence and specificity for myeloperoxidase (MPO-ANCA).

However, ANCA can be demonstrated in patients with inflammatory disease due to irritable bowel disease (IBD), autoimmune liver disease, rheumatoid arthritis (RA), drug-induced vasculitides and infections, often with multiple antigen specificities and unclear clinical significance. Accurate identification of all patients with AAV and the avoidance of misdiagnosis can be achieved by use a "gating policy" based on clinical information given to the laboratory at the time of request. This policy limits requests for ANCA testing exclusively to clinical scenarios that may suggest a diagnosis of necrotizing vasculitis.

The clinical utility of serial ANCA measurements for predicting and assessing clinical relapses is under discussion, but may be informative in subsets of patients, such as patients with renal involvement or alveolar hemorrhage and in patients treated with rituximab.

The new testing strategy for ANCA in vasculitis directly identifies the ANCA target antigen (PR3- and MPO-ANCA) and has a particular value for the AAV sub classification. Indeed, new studies have shown that AAV can be classified based on ANCA serotype, since PR3- and MPO-ANCA- diseases are strongly associated with distinguishable genetic alleles, different clinical and histological features. ANCA presence and the antigen specificity also may have important value as a prognostic factor and may serve as a guide for immunosuppressive therapy. This chapter considers current data on ANCA testing, the application of particular ANCA assays, and how such testing can be used in the management of patients with small-vessel vasculitis.

ANCA TESTING IN SMALL-VESSEL VASCULITIS

According to the international consensus statement of 1999 [5], ANCA testing by IFT for screening followed by mandatory antigen-specific ELISA for positive IFT tests [5, 6] has become the standard in many laboratories. The three major patterns demonstrated with IFT (Figure 1). The first is granular cytoplasmic neutrophil fluorescence with central interlobular accentuation ("C-ANCA") so noted overall in 90% of patients, in particular in active generalized GPA. The second is perinuclear neutrophil staining often with nuclear extension

(“P-ANCA”) so noted in those with MPA and EGPA. So-called “atypical” patterns are infrequent, comprising a mix of cytoplasmic and perinuclear fluorescence, with multiple antigen specificities such as in association with drug exposure, IBD and RA, most often in the absence of vasculitis [4]. However, the interpretation of IFT patterns can be tricky even for experienced laboratories, and studies have shown that misinterpretation can happen frequently. IFT is also a time consuming method, followed by ELISA as a two-step process even more so.

The alternative to conventional IFT is *image analysis*, which quantifies fluorescence in a single dilution of a patient sample in comparison with the intensity of standardized calibrators. Evaluation of the image analysis for the potential to detect ANCA in a cohort a consecutive PR3-ANCA positive GPA patients [10] revealed detectable ANCA levels in 75% of patients at the time of renal relapse, indicating a lower diagnostic sensitivity as compared with IFT and capture ELISA (100%). Quantitative image analysis predicted disease relapse somewhat better than IFT, but was comparable to direct ELISA [9].

Due to significant differences in sensitivity, specificity and predictive value among commercially available ANCA ELISA kits the combined method of IFT and ELISA have been shown to provide the highest diagnostic performance in a meta-analysis [22]. In recent years, many new developments for ANCA testing have become available. New solid phase methods like chemiluminescent immunoassays (CLIA), addressable laser bead immunoassays, fluorescent-enzyme immunoassays (FEIA) and line or dot immunoassays as well as IFT assays have become commercially available.

Figure 1. ANCA immunofluorescence patterns on ethanol-fixed neutrophils. (a) C-ANCA; (b) P-ANCA; and (c) A-ANCA.

A *multiplex* technology offers the unique opportunity to detect the presence of multiple autoantibodies at the same time and in the same sample. This new automated immunoassay builds on a synthesis of bead-based multiplex assays and flow cytometry. Trevisin and colleagues [11] compared the performance of a flow cytometric immunoassay for PR3 and MPO-ANCA with IFT and ELISAs in active and treated vasculitis and inflammatory bowel disease and found a specificity of 88% compared with 96% and 94% respectively for IFT and both ELISA. The PR3- and MPO-ANCA immunoassay was almost as sensitive as IFT, and more sensitive than, but just as specific as most ELISA in detecting ANCA in active and treated vasculitis [11]. A major advantage of this assay is the ability to screen simultaneously for a panel of autoantibodies relevant to vasculitis, however, prospective studies are needed this automated method in the initial screening of patients with suspected vasculitis.

With the emergence of new detection technologies, a comparative study to challenge current recommendations seemed required. In 2016 a multicenter study [21] led by the European Vasculitis Society (EUVAS) compared sensitivity and specificity of various antigen specific immunoassays and IFT. The results showed no significant difference for several classical ELISA, automated FEIA, chemiluminescence assay, multiplexed flow immunoassay and multiplexed microbead IFT assay. Furthermore, the study showed a significant difference and high variability in the performance of IFT at two expert laboratories. Differences between automated multiparameter IFT devices were also observed. Thus, the diagnostic value of immunoassays is at least as high as, if not better than IFT [21].

In 2017, a revised international consensus on ANCA detection has been published [1]. Screening for ANCA by high-quality immunoassays is recommended as the preferred method. IFT adds little value to ANCA screening, especially if the pre-test probability for AAV is high. If test results for both PR3-ANCA and MPO-ANCA are negative, yet the clinical likelihood of small-vessel vasculitis is high, then using another immunoassay or IFT, or referral to an experienced laboratory is recommended.

DIAGNOSTIC SIGNIFICANCE OF ANCA

Whereas PR3- and MPO-ANCA have been shown to be highly specific for AAV, the diagnostic value of such testing in other non-vasculitic conditions is very limited. An overestimation of the diagnostic relevance of a positive ANCA test may erroneously misdirect clinicians and delay adequate treatment. ANCA-positivity has been noted in diverse autoimmune disorders. Among them the connective tissue diseases systemic lupus erythematosus, RA, and Felty syndrome; the gastrointestinal disorders including ulcerative colitis, Crohn disease, and autoimmune hepatitis; infectious disorders including tuberculosis, leprosy, and subacute bacterial endocarditis; malignancy, and in association with the drugs propylthiouracil, hydralazine, and illicit cocaine use. Since the diagnostic accuracy of ANCA testing in vasculitis should be improved by an increased pretest probability, it makes sense that such testing should be guided by the likelihood of AAV. According to the consensus statement [1], adherence to clinical ordering guidelines for ANCA, testing can reduce the number of false-positive tests by 27% without missing a single patient with AAV [12]. A symptom related gating policy for ANCA testing could reduce the total number of ANCA tests performed by more than 20% with appreciably increased efficiency and cost saving.

Arnold and colleagues [13] investigated the impact of a gating policy at a single regional center in the year prior to and following the consensus guidelines [5] to ensure appropriate usage by auditing clinical outcomes in patients in whom ANCA testing was declined and documenting the absence of either GPA or MPA in all so studied. Their findings demonstrated that adherence to gating policy for ANCA testing coupled with close liaison between clinician and laboratory does not result in either a missed or delayed diagnosis of a small-vessel vasculitis belonging to the GPA-MPA spectrum.

ANCA LEVELS AND DISEASE ACTIVITY

The clinical usefulness of measuring ANCA levels in relation to disease activity and in guiding therapy is still controversial. Although ANCA titers are typically high at presentation and predictably relate to disease activity [14], there are potential confounders of the relationship between ANCA levels and disease activity including, publication bias against negative results, definition of relapse, intensity of clinical screening for disease activity, intervals of follow-up visit, and variable methods and intervals employed in sequential ANCA detection. A rise in serial ANCA measurements in patients with AAV presumably in remission status can be a clue to the prediction of disease relapse. However ANCA levels should not be used alone to guide treatment. Notwithstanding, a significant increase in ANCA levels or the reappearance of ANCA in the proper clinical and histopathological context, may suggest the need for more attentive management.

PR3- AND MPO-ANCA-SUBTYPES

Of all the possible known ANCA target antigens, only two, PR3 and MPO are closely associated with small-vessel vasculitis. Extra renal manifestations, granuloma formation and relapse were more frequent in patients with PR3-ANCA than in those with MPO-ANCA [15, 16]. Among 173 patients screened at the time of diagnosis with renal biopsy tissue, both active and chronic renal lesions were more common in MPO-ANCA-positive than PR3-ANCA-positive [17]. Despite substantial overlap, there were clinical and pathologic differences between patients with PR3-ANCA and MPO-ANCA that may reflect different pathogenic interactions between ANCA, their target antigens, and organ involvement at the molecular level. A genome-wide association study [18] confirmed a genetic component in the pathogenesis of AAV revealing distinctions between GPA and MPA that were associated with ANCA specificity, suggesting that the response against PR3-ANCA was a central pathogenic feature of PR3-ANCA associated vasculitis. Moreover, the strongest genetic associations were with antigenic specificity of ANCA, not the clinical syndrome. *HLA-DP* and the genes encoding α_1 -antitrypsin (*SERPINA1*), proteinase 3 (*PRTN3*) were associated with PR3-ANCA specificity, whereas MPO-ANCA was associated with *HLA-DQ*.

About 10% of patients with GPA do not have demonstrable ANCA by IFT or antigen specific assays and are likely to have localized disease. Moreover, ANCA-negative patients and generalized GPA tend to be younger in age, more likely to be of female gender, with less

lung and kidney involvement, lower rate of relapse, and improved outcome compared to those ANCA-positive patients.

Since ANCA specificity seems to affect the phenotype of small vessel vasculitis, the initial response to remission-inducing drug therapy, long-term prognosis and relapse risk more than the clinical diagnosis, it has been suggested that classification of AAV by ANCA specificity could provide more useful information than clinical diagnosis [19].

CONCLUSION

ANCA serology and the associated clinical manifestation of AAV continue to attract the attention of clinicians and investigators alike. In addition, to be providing a useful diagnostic tool for small vessel vasculitis, ANCA testing may be useful in predicting relapses and in guiding therapy. Worldwide, most laboratories currently perform IFT to screen for ANCA positivity patients with small-vessel vasculitis, with later confirmation employing PR3- and MPO-ANCA immunoassays. However, in recent studies new high-quality antigen-specific immuno-assays have been shown to have equal or better diagnostic performance than IFT. Therefore, the new international consensus of 2016 recommends screening for ANCA with immunoassays primarily since there is no apparent benefit of combining it with IFT. Notwithstanding, any testing strategy applicable to vasculitis should be able to identify relevant ANCA target antigens since these correlate best with the clinicopathological aspects, disease activity, and propensity for relapse. The solution to problems regarding ANCA-diagnosis lies in focusing upon the implementation of high-quality immunoassay testing according to the revised international consensus, and restriction of such tests to those with the highest pretest probability of AAV.

ABSTRACT

Anti-neutrophil cytoplasm antibody (ANCA)-associated vasculitides (AAV) include several distinct multi-systemic disorders, the diagnoses of which rely on recognition of a compatible clinical syndrome supported by radiological, immunological and histological laboratory findings. If unrecognized, there may be significant delays in treatment culminating in multi-organ morbidity. The pathogenesis of AAV is complex, involving both innate and adaptive immune systems, with loss of tolerance to autoantigens leading to the production of antibodies that activate cytokine-primed neutrophils. The factors leading to production of ANCA are incompletely understood, but may involve cross-reactivity to bacterial antigens and the expression of complementary peptides. T-cells appear to play a role in both loss of self-tolerance and in the cause of tissue injury. Moreover, peripheral blood T-cells show evidence of persistent activation driven partly by cytomegalovirus infection. Activation of the alternative complement pathway has recently emerged as a significant pathogenic mechanism in the development of glomerulonephritis in AAV.

INTRODUCTION

Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are a group of rare life-threatening autoimmune disorders that includes microscopic polyangiitis (MPA) and its renal limited variant (RLV), granulomatosis with polyangiitis (GPA, previously known as Wegner’s granulomatosis), and eosinophilic granulomatosis with polyangiitis (EGPA; previously known as Churg-Strauss syndrome (CSS)). Although these diseases can manifest in many different ways, there is significant overlap between GPA, MPA and RLV in clinical features, presentation, pathogenesis and treatment. This article reviews the current understanding of classification and pathogenesis of MPA, RLV and GPA.

EPIDEMIOLOGY

AAV are rare diseases with an annual incidence of <10 per million population [1, 2] and peak age of onset in the seventh and eight decades [3]. They form a highly heterogeneous group, both in terms of severity and organ involvement, and thus manifest in a wide variety of clinical presentations.

NOMENCLATURE AND CLASSIFICATION

Although there are no diagnostic criteria, the Chapel Hill Consensus Conference (CHCC) (Table 1) [4] provided useful nomenclature and definitions for the classification of the vasculitides, classifying AAV as small-vessel vasculitides (SVV) according to the caliber of the vessels involved and associated clinicopathological features. Subsequently, the European Medicines Agency (EMA) algorithm was developed to accurately classify patients with AAV for epidemiological studies [5, 6]. This algorithm employs clinical, serological, histological and radiological criteria to minimize the problem of patients being unclassified or assigned to overlapping categories. Table 2 shows an extent and severity categorization of AAV utilized by the European Vasculitis Study Group [7]. Revised classification criteria and validated diagnostic criteria are currently under development.

Table 1. Chapel Hill Consensus Conference on the nomenclature of systemic vasculitis: definitions [4]*

Granulomatosis with polyangiitis (Wegener’s) (GPA)	Granulomatous inflammation involving the respiratory tract, and necrotizing vasculitis affecting small to medium-sized vessels (e.g., capillaries, venules, arterioles, and arteries). Necrotizing glomerulonephritis is common.
Microscopic polyangiitis (MPA)	Necrotizing vasculitis, with few or no immune deposits, affecting small vessels (i.e., capillaries, venules, or arterioles). Necrotizing arteritis involving small and medium-sized arteries may be present. Necrotizing glomerulonephritis is very common. Pulmonary capillaritis often occurs.
Renal limited vasculitis (RLV)	Pauci-immune necrotizing glomerulonephritis with no apparent extra-renal features at presentations.

*Adapted from reference 4.

Table 2. European Vasculitis Study Group disease extent and severity categorization for antineutrophil cytoplasmic antibody-associated vasculitides [7]*

Category	Definition
Localized	Upper and/or respiratory tract disease with systemic involvement or constitutional symptoms
Early systemic	Any, but without any imminent organ-threatening or life-threatening disease
Generalized	Renal or other organ-threatening disease with serum creatinine <500µmol/L (5.6mg/dL)
Severe	Renal or other vital organ failure with serum creatinine >500µmol/L (5.6mg/dL)
Refractory	Progressive disease unresponsive to glucocorticoids and cyclophosphamide

*Adapted from reference 5.

CLINICAL PRESENTATION

The clinical presentation can be divided into systemic symptoms and organ-specific symptoms, the former commonly including fever, night sweats, malaise, weight loss, arthralgia and myalgia which may occur multiply and wax and wane over several months [8]. About 96% of patients with GPA and 88% of those with MPA have systemic symptoms at presentation [9]. Due to the highly variable presentation and lack of diagnostic criteria there may be significant delay in establishing the diagnosis in GPA and MPA, with respective median times from symptom onset to diagnosis of 4.5 and 6 months [9]. The single most notable difference between GPA and MPA or RLV is the presence of granulomata in GPA which are not seen in MPA or RLV.

Ophthalmic

AAV may cause inflammation of various structures of the eye including the lids and nasolacrimal system. Lane and colleagues [9] described ophthalmic involvement in 40% of patients with GPA at the time of presentation compared to 4% of those with MPA; and in 48% of patients with GPA at some point during the disease. Such involvement ranges from mild inflammation to severe sight-threatening inflammation with episcleritis, conjunctivitis, scleritis, keratitis, uveitis, and retinal vasculitis [10]. Eye redness may be painless or severely painful, and proptosis, diplopia and visual loss may occur secondary to retrobulbar orbital pseudotumor [11]. Intra-ocular granulomata may also develop and need to be differentiated from tumors. Nasolacrimal duct obstruction occurs in approximately 10% of patients with GPA and results in chronic epiphora and places patients at increased risk of chronic infection [10]. Fibro-vascularization of the palpebral surface of the eyelids may result in entropion and trichiasis [12, 13]. Optic nerve ischemia may also occur [8].

Ear, Nose and Throat (ENT)

Up to 77% of patients with GPA will have upper respiratory tract symptoms at presentation compared to 29% of those with MPA [9]. Nasal disease is more common than

deafness and middle ear involvement in both GPA and MPA. More than 90% of patients with GPA develop ear and upper airway disease [14, 15]. Typical nasal symptoms of GPA include rhinitis, nasal stuffiness and pain, epistaxis, and brown or bloody crusting. The characteristic “saddle-nose deformity” is secondary to septal erosion due to chronic nasal inflammation. Patients with GPA are at increased risk of nasal and sinus infections due to chronic damage which increases the difficulty in differentiating secondary infection from disease activity.

Middle ear involvement in GPA presents as conductive hearing loss with the commonest cause being Eustachian tube dysfunction secondary to nasopharyngeal disease [16, 17]. Sensorineural hearing loss is due to inner ear disease which may also be associated with vestibular dysfunction with some patients presenting with vertigo and balance disturbance [17, 18]. The mechanism of inner ear involvement in GPA is poorly understood when compared to middle ear involvement [19].

Involvement of the trachea may present with pain, cough, hoarseness, wheezing or stridor, however it is often asymptomatic at onset. The development of subglottic or bronchial stenosis can lead to severe dyspnea requiring tracheostomy or reconstruction [11].

Pulmonary

Pulmonary involvement occurred at presentation in 63% of patients with GPA compared to 29% of those with MPA [9]. Pulmonary manifestations range from new-onset asthma and ‘antibiotic-resistant’ pneumonia to life-threatening alveolar hemorrhage. In those with GPA the symptoms may be due to single or multiple lung nodules and granulomata, and may be misdiagnosed as cavitating infectious or neoplastic lesions; mediastinal and hilar lymphadenopathy may also occur [20]. Pulmonary capillaritis is responsible for lung hemorrhage and rapidly changing alveolar infiltrates and should be suspected in patients with falling hemoglobin levels in conjunction with hemoptysis and dyspnea. Those with MPA may also develop pulmonary interstitial fibrosis [21]. Other indicators of pulmonary involvement include wheezing, productive or non-productive cough, and exertional dyspnea. [8].

Renal

This is often a severe manifestation of AAV [3] that affects an estimated 77% of patients with GPA and 92% of those with MPA at presentation [9]. Renal vasculitis presents with proteinuria, hematuria, and red cell casts due to focal necrotizing glomerulonephritis [22]. It can lead to rapid deterioration of renal function with eventual dialysis dependency. Hematuria may be visible or non-visible, while proteinuria is usually insufficient to cause nephrotic syndrome [8]. Renal biopsy is the most appropriate method of identifying and prognosticating glomerulonephritis in AAV [23, 24].

Nervous System

AAV can affect the peripheral (PNS) and central nervous system (CNS), as observed in 19% of patients with GPA and 17% of those with MPA at presentation [9]. Involvement of

the PNS usually manifests as motor or sensory deficits in a mononeuritis multiplex or distal sensory polyneuropathy distribution. While typically painless in the acute stage, pain syndromes commonly develop as a result of neuro-regeneration. Involvement of the CNS occurs in 8% of patients with AAV at presentation [15], presenting with weakness, dysphagia, blindness or other CNS disturbances [25]. Three distinct patterns of CNS involvement have been identified: during the generalized phase the small and medium sized vessels of the CNS can become inflamed; secondly, localized granulomatous masses from the upper respiratory tract may invade the CNS; thirdly, granulomata may develop within CNS structures [26].

Cutaneous

Cutaneous involvement occurs in 42% of GPA and 25% of MPA patients at diagnosis [9]. A wide range of signs are seen that include purpura, papules, urticaria, infiltrative erythema, infarction and splinter hemorrhage, ulcerated nodules, livedo reticularis, and digital gangrene [27]. The type of lesion is determined by the size of the blood vessel affected. The most common manifestation is a palpable purpuric rash beginning along the lower extremities that may become ulcerated or vesicular. The urticarial rash seen in vasculitis can be differentiated from allergic non-vasculitic urticaria by the fact that it will usually last for more than one day and may progress to purpuric lesions [28].

Cardiac

Direct cardiac involvement is uncommon in either GPA or MPA however the former may be associated with coronary arteritis, pericarditis and valvular disease. Endocarditis can occur as a result of aortic valvular lesions [29]. MPA may be associated with pericarditis, heart failure and hypertension however the incidence is very low [30].

Gastrointestinal

Gastrointestinal involvement occurs at presentation in up to 30% of patients with AAV [14, 31-33]. Gastrointestinal involvement may present with ischemic or vasculitic colitis, bloody diarrhea, pain and progression to ulceration, perforation and infarction [11, 34]. 30-56% of patients with MPA have been found to have GI involvement [35, 36], the commonest presenting symptom of which was pain, noted in 97% of patients, followed by nausea, vomiting, diarrhea, melena, and hematemesis [37]. Rarely, other intra-abdominal organs can be involved such as the gallbladder and pancreas [34].

ETIOPATHOGENESIS

There is evidence for a pathogenic role of ANCA in the etiopathogenesis of inflammation and organ damage mediated by immune mechanisms. With regards to the innate immune

system, neutrophils play a pivotal role in the effector phase causing organ and tissue damage. Complement activation, particularly the alternative pathway, seems to be important in glomerulonephritis. The adaptive immune system is important in the development of autoimmunity with the production of autoantibodies against proteinase 3 or myeloperoxidase by B-cells and there is increasing evidence for a pathogenic role for T-cells. Genetic susceptibility factors are encoded by certain human leukocyte antigen (HLA) haplotypes [38], notably *HLA-DPB1*0401* alleles are associated with an increased risk for development of GPA [39], while *HLA-DRB1*0901* is associated with MPA [40]. In addition, the *DRB1*15* haplotype was associated with anti-PR3 AAV in African American patients [41]. Polymorphisms of genes involved in the control of the immune system and associated with increased risk of vasculitis include *CD226*, *PTPN22* protein, *CTLA-4*, *IL-10*, and *TLR9* [42-47], although none are specific for AAV. A recent genome-wide association study correlated single-nucleotide polymorphisms in *HLA-DPB1* and *PRTN3* with frequency of autoreactive T-cells and neutrophil expression of PR3 [48], thus providing a functional link between genetic risk factors and the immunopathology of AAV.

Copy number variation of *FcγR3b* and human β -defensin (*DEFB4*) may represent further important mechanisms in AAV susceptibility [42, 49]. Genes expressed by memory T-cells as well as a *CD8+* T-cell transcription signature have been described in both systemic lupus erythematosus and AAV with associated poorer outcome. This signature is thought to comprise enriching genes involved in the *IL-7* receptor and T-cell receptor signaling pathway [50].

Recent work by Yang and colleagues [51] has addressed the contribution of epigenetic mechanisms to AAV pathogenesis. Chromatin immunoprecipitation (ChIP) performed on peripheral blood neutrophils demonstrated an association between specific histone modifications at the *MPO* and *PRTN3* loci and active AAV. However, it is unclear whether these histone modifications in themselves play a pathogenic role.

Carriage of the dysfunctional *z* allele of the α -1-antitrypsin (*A1AT*) gene is associated with an increased risk of developing AAV and predicts more severe outcomes [52-57]. Patients carrying the *z* allele not only have an increased risk of AAV but also have increased concentrations of circulating *A1AT* polymers capable of priming circulating neutrophils for ANCA-induced activation [58].

Environmental factors may also have a role in disease development. Provocation of an immune response and inflammation is thought to occur after exposure to silica dust with 22-46% of patients with AAV having documented exposure to silica prior to disease development. It is proposed that exposure results in accelerated apoptosis of macrophages and polymorphonuclear leukocytes, thereby triggering disease development [59, 60].

Infectious triggers have also been implicated in the etiopathogenesis of AAV. A contributory role of low-grade *Staphylococcus aureus* infection in the etiopathogenesis of AAV has been suggested based on the observation that 63% of patients with GPA had chronic nasal carriage when compared with 20% of control individuals [61]. Moreover, nasal carriage has been associated with disease relapse [61, 62], and patients who received maintenance co-trimoxazole treatment were observed to have fewer relapses [63]. A study of bronchioalveolar lavage fluid (BALF) in GPA patients identified increased levels of infection compared to controls and demonstrated that BALF was permissive for bacterial growth [64].

Molecular mimicry may also underlie the development of necrotizing and crescentic glomerulonephritis (NCGN) through infection with fimbriated bacteria, such as *Escherichia*

coli and *Klebsiella pneumonia* [65]. The bacterial adhesion protein FimH was found to be homologous to a major epitope of LAMP-2 which is in turn recognized by anti-LAMP-2 antibodies in pauci-immune NCGN [66, 67] although these results have not been replicated by other researchers [68].

The development of AAV has been linked to several drug exposures, most commonly propylthiouracil with a prevalence of ANCA expression ranging from 4% to 46% [69, 70]. D-penicillamine, hydralazine and minocycline have also been associated with disease. Sulphasalazine, and other similar drugs, may increase autoantibody production as they induce apoptosis which in turn increases expression of ANCA antigen targets on the surface of apoptotic neutrophils [71, 72].

ANCA PATHOGENICITY

Since the discovery of ANCA there has been considerable debate as to whether or not it has a direct pathogenic role with most authors now accepting that anti-myeloperoxidase (MPO) antibodies are pathogenic based on the results of clinical, laboratory and animal studies. Proteinase 3 (PR3) was found to be the target antigen of the cytoplasmic-ANCA indirect immunofluorescence pattern while MPO is the target antigen of the perinuclear-ANCA pattern, with the specificity of PR3-ANCA and MPO-ANCA for AAV as high as 98% [73, 74].

Clinical Evidence for ANCA Pathogenicity

The most striking clinical evidence for the pathogenicity of ANCA was the report of a neonate developing pulmonary hemorrhage and glomerulonephritis caused by transplacental transfer of ANCA IgG from the mother who had anti-MPO antibody positive MPA [75]. There has, however, been a lack of clear consistent evidence of a relationship between the serum ANCA titer and disease activity [76-79]. A meta-analysis of studies investigating the association between ANCA and disease activity found a rise in the serum ANCA titer and persistent presence of ANCA was only modestly predictive of future disease relapse, suggesting that serial ANCA measurements had a limited utility in guiding treatment decisions in individual patients [80]. It is possible that there are subtle changes in ANCA such as glycosylation state or change in the predominant subclass that are related to disease activity and undetected by routine assays [81-84].

Animal Models of AAV

Several murine and rat models of anti-MPO AAV have been created; unfortunately to date there has not been a suitable animal model for anti-PR3 [85-87]. Xiao and colleagues [88] immunized MPO-/- mice with purified MPO to generate high avidity anti-MPO antibodies. Granulomatous inflammation, necrotizing and crescentic glomerulonephritis, and systemic necrotizing vasculitis developed when mouse splenocytes were transferred to Rag2-

/- mice or when anti-MPO containing IgG was transferred to wild-type mice. Levels of tumor necrosis alpha (TNF- α) were increased and renal injury enhanced when lipopolysaccharide (LPS) was added. The importance of cytokines in the pathogenic process was emphasized by the finding that these effects could be ameliorated by addition of anti-TNF- α antibodies [88]. Prominent macrophage and neutrophil invasion was found at sites of glomerular injury which, along with the observation that crescentic glomerulonephritis did not develop in neutrophil-depleted mice, supports the important role of neutrophils in the pathogenesis of AAV [89].

Leukocyte adhesion and transmigration were shown by intravital microscopy to be enhanced by anti-MPO IgG in wild-type mice pre-treated with cytokines. β 2-integrins (CD18) and Fc γ receptors were shown to be necessary as recruitment was not seen following the co-administration of anti-CD18 antibodies or in Fc receptor γ chain-/- mice [90]. Kuligowski and colleagues [91] found that high-dose anti-MPO induced β -integrin dependent adhesion in the absence of LPS, while LPS was necessary to induce adhesion at low doses of anti-MPO.

***In vitro* Activation of Neutrophils by ANCA**

In vitro work on the effect of patient-derived IgG containing ANCA demonstrated ANCA-activation of cytokine primed neutrophils. During the priming process, MPO and PR3 were translocated to the plasma membrane of neutrophils where they can interact with ANCA [92-94]. In addition to increasing surface expression of ANCA, interleukin (IL)-18, TNF α and granulocyte macrophage colony stimulating factor lead to mobilization of nicotinamide adenine dinucleotide phosphate (NADPH) oxidase complex components necessary for superoxide generation [94-97]. Subsequent crosslinking between ANCA and Fc γ receptors and ANCA antigens results in degranulation, production of pro-inflammatory cytokines, adhesion to endothelium and generation of superoxide with multiple signaling pathways implicated [98-103] (Figure 1). Neutrophil gene expression is also induced by binding of both intact ANCA and F(ab')₂ portions [104].

Abbreviations: Cbl, Casitas b-lymphoma protein; cPKC, protein kinase C; DAG, diacylglycerol; DGK, diacylglycerol kinase; G_i, G protein; IP3, inositol 1, 4, 5-triphosphate; PI3K, phosphatidylinositol 3-kinase; PIP3, phosphatidylinositol 3, 4, 5-triphosphate; PIPKin, phosphatidylinositol-4-phosphate-5-kinase; PLC γ , phospholipase C γ ; PtoH, phosphatidic acid; Src, tyrosine kinase; Syk, spleen tyrosine kinase.

Figure 1. Summary of the neutrophil intracellular signaling pathways activated by ANCA cross ligation of MPO or PR3 and Fc γ receptors. This activation results in superoxide production, degranulation and adhesion to the endothelium. Separate pathways are activated by either interaction with the ANCA antigens or Fc γ receptors. Signaling must be induced via both pathways for full neutrophil activation, which is highlighted by the protection to development of vasculitis demonstrated in mice lacking phosphatidylinositol-3 kinase γ .

Effect of ANCA on Neutrophil-Endothelium Adhesion

Endothelial necrosis is a histological feature of small vessel disease in AAV, with exposure of the basement membrane leading to platelet aggregation, thrombosis and occlusion [105]. Swelling, necrosis and dehiscence of endothelial cells is an early histological feature and thought to be mediated by ANCA activation of cytokine-primed circulating neutrophils. This results in neutrophil adhesion to and transmigration through endothelium, associated with neutrophil degranulation and production of superoxide. Adhesion and transmigration of leukocytes is promoted by the release of chemoattractant proteins by endothelial cells and upregulation of adhesion molecules. The serum concentrations of soluble factors associated with this process include vascular endothelial growth factor (VEGF), inter-cellular adhesion molecule (ICAM)-3, P-selectin, thrombomodulin, angiopoietin-2, matrix metalloproteases 1, 3, and 9; endothelial microparticles and stem cells [106-112].

In vitro studies showed that ANCA stabilized adhesion and promoted transmigration of neutrophils flowing over endothelial cells [113]. In shear stress models employing human endothelial cells and healthy donor neutrophils, this interaction depended on the interaction between neutrophil-expressed CXCR1 and CXCR2, and CD18/CD11b and their ligands on endothelial cells, [113-115]. An MPO-/- animal model demonstrated stimulation of neutrophil-endothelial adhesion dependent on the action of CD18 [90].

In activated neutrophils, intracellular F-actin polymerizes making the neutrophil more rigid and less deformable. This may lead to retention of neutrophils in small diameter capillaries and increased contact with endothelium, promoting damage leading to cell detachment and lysis [116, 117]. One study demonstrated reduced CXCR1 and CXCR2 expression on neutrophils from AAV patients, even those in remission where expression showed an inverse relationship with serum IL-8 concentrations. Reduced chemokine receptor expression impaired endothelial transmigration but not adhesion, which may increase contact with endothelium and promote intra-vascular retention of activated neutrophils [118]. The actions of endothelial cells inhibit the neutrophil production of superoxide, implying that granule content release may be a more important pathogenic mechanism in AAV [89-91].

ANCA and Neutrophil Cell Death

Neutrophil apoptosis does not normally result in the release of the intracellular contents, thus preventing inflammation. ANCA-activated neutrophils were shown to undergo dysregulated and accelerated apoptosis which may lead to increased inflammation associated with the release of granule contents, increased surface expression of MPO and PR3, and macrophage-mediated uptake of ANCA opsonized neutrophils [71, 119, 120].

More recently, there has been increasing focus on the relationship between ANCA and neutrophil extracellular trap (NET) formation. NETs are reticular structures released by activated neutrophils, composed of decondensed chromatin and associated antimicrobial proteins [121]. Since the first description of their structure in 2004, NETs have been implicated in the pathogenesis of a range of inflammatory and autoimmune disorders [122].

Kessenbrock and colleagues first demonstrated the presence of NETs in glomeruli from AAV patients [123], suggesting a potential role in mediating tissue damage. Since then, NETs were shown to be more prevalent in nerve tissue from patients with MPA neuropathy than other types of neuropathy [124], and circulating levels of NET remnants were found to be increased in AAV patients compared to healthy controls [125]. Individual case reports identified NETs in cutaneous lesions [126] and thrombus [127] from AAV patients. Taken together, these findings suggest that NETs could play a role in mediating autoimmune damage in multiple organ systems. Notably, ANCA-induced NETs associate with alternative complement pathway components C3b and C5b-9 in human serum, with subsequent activation of the alternative complement pathway *in vitro* [128]. This provides a possible link between NETosis and mechanisms of complement-mediated damage in AAV.

Kessenbrock and colleagues also showed that ANCA could stimulate neutrophils to release NETs [123]. Interestingly, independent work found that neutrophils from AAV patients exhibited increased NET production compared to neutrophils from healthy controls when stimulated with ANCA [129]. MPO-ANCA affinity but not titer correlated with increased levels of NETs in AAV patients [40], and the pro-inflammatory mediator high-mobility group box 1 (HMGB1) was identified as an additional factor that potentiates ANCA-induced NET release *in vitro* [130]. In addition, there is evidence that NET degradation is impaired in serum from MPA patients [131], which could contribute to both NET-induced tissue damage and immunogenicity.

Since NETs represent a source of autoantigens PR3 and MPO, it is possible that disordered NETosis plays a role in the induction of autoimmunity. Sangaletti and colleagues loaded myeloid dendritic cells (mDCs) with NET components and transferred them into naïve mice [132]. This induced circulating PR3- and MPO-ANCA and resulted in pulmonary-renal vasculitis. In contrast, injection of mDCs co-cultured with apoptotic neutrophils resulted in autoantibody production in the absence of this disease phenotype. This study demonstrated that NET components are able to induce ANCA-like disease in a murine model, implying that NETs represent a potential source of autoantigens in AAV. Therefore, NETosis may contribute to a positive feedback loop in which ANCA induce both NET-mediated tissue damage and the exposure of NET-derived autoantigens. However, this model does not explain how tolerance to these autoantigens is broken, and thus far there is limited evidence that this process plays a pathogenic role in humans.

Cell-Mediated Immunity

Both B- and T-cells have important roles in the pathogenesis of AAV and are important in the induction of autoimmunity and the development of tissue inflammation. The production of autoantibodies, implying a loss of self-tolerance to PR3, MPO and possibly LAMP-2, could occur via several possible mechanisms. The presence of low levels of specific autoantibodies (SAA) to MPO and PR3 in the healthy population has led to the theory that ANCA form part of the natural repertoire [133]. One explanation for the non-pathogenic nature of SAA is that compared to MPO-ANCA derived from patients with AAV, significantly lower titers of SAA MPO are found with lower avidity suggesting that high affinity autoantibodies underlying the autoimmune pathology of AAV may result from

dysregulation of SAA-producing B-cells. However, the precise mechanism remains unknown and larger cohort studies are required [133]. One intriguing suggestion has been the role of complementary peptides in the production of anti-PR3 ANCA. These peptides are produced by the transcription and translation of the DNA complementary to the PR3 gene. The peptides so produced generate an anti-complementary PR3 (cPR3) response which leads to an anti-idiotypic response producing anti-PR3 antibodies [134]. It has also been suggested that cPR3 shows homology with proteins from staphylococcal bacteria. T-cells specific for cPR3 have also been identified in AAV patients [135].

T-cells are required to allow IgG subclass switching, a process which has been shown to be essential in the pathogenesis of AAV [136]. The importance of T-cells in the disease process is further supported by the presence of high levels of soluble IL-2 receptors and activated CD4⁺ cells in patient blood and sera, as well as soluble CD4 and CD8 [137]. MPO and PR3 have been shown to promote the proliferation of autoreactive T-cells [138-140].

Regulatory CD4⁺ T-cells (Treg) important in the maintenance of self-tolerance have functional defects in patients with GPA in remission [141, 142]. The percentage of Treg cells was found to be inversely related to the disease relapse rate in patients with GPA and was associated with both functional and numerical defects in PR3-specific Treg cells [143].

There has been increasing interest in the role of IL-17 producing helper T-cells (Th17) in autoimmune disease in which higher proportions of Th17 cells were found in the peripheral blood of AAV patients compare to controls [144]. Furthermore, in patients with GPA there was expansion of the effector Th17 population and increased IL-17A production by T-cells stimulated with aCD3/aCD28 *in vitro* [145]. MPO-specific Th17 cells were identified in AAV patients with MPO-ANCA, suggesting a pathogenic role [146]. Mice deficient in IL-17A were almost completely protected from developing GN in an anti-MPO model of vasculitis [147].

T-cells are prominent at sites of inflammation in AAV particularly in the kidney where they are the predominant infiltrating cell type [148]. Four major subtypes, Th1, Th2, Th17 and Treg, were identified in inflamed AAV tissue [149-152]. The presence of interstitial Foxp3-positive Treg predicted renal survival in patients with MPO ANCA-associated glomerulonephritis, suggesting a beneficial role in suppression of inflammation [153].

Large populations of T-cells and macrophages have been found in the granulomatous and vasculitic lesions in AAV and studies have demonstrated the involvement of CD4⁺ T cells in AAV disease manifestation, particularly effector memory T cells (T_{EM}) [154]. The theory that CD4⁺ cells migrate to sites of inflammation in AAV was supported by the observation of decreased levels of peripheral blood CD4 T_{EM} in patients with GPA with active disease compared to those in remission [154]. Moreover, the observation that T-cell depletion is effective in controlling disease in therapy-resistant patients supports their role in inflammation [155]. GPA patients in remission were found to have a significantly increased circulating proportion of Th17 effector memory cells and decreased proportion of Th1 effector memory cells compared to healthy controls [156]. The degree of this aberrant distribution of T_{EM} subsets was associated with tendency to relapse and multi-organ disease involvement, providing further evidence for the pathogenic importance of the Th17 response in AAV.

One particularly interesting population of Th cells in AAV is the frequently reported expanded population of CD4⁺CD28⁻ cells which has been associated with increased disease severity [154, 157-161]. CD4⁺CD28⁻ cells have potent effector functions and are a major

source of Th-1 type cytokine secretion, predominantly IFN γ and TNF α and express perforin and granzyme B [162]. The expansion of this cell population is driven by cytomegalovirus infection in AAV, and was no difference between AAV patients and controls matched for CMV-specific IgG seropositivity. Recent evidence showed that prior infection with both Epstein-Barr virus (EBV) and CMV was associated with increased percentage of peripheral CD4+CD28- cells compared to either infection alone in the context of GPA [163]. The expansion of this population in AAV patients was associated with a reduced number of naïve helper T-cells and an increased risk of infection and mortality [164].

B-cells are responsible for the production of ANCA and are thus vital in the pathogenesis of AAV. Tissues affected by GPA, such as nasal lesions, contain B-cells [148, 165] and the proportion of activated B cells is increased in active GPA [158]. That treatment with the B-cell depleting anti-CD20 monoclonal antibody rituximab has been shown to induce disease remission and reduce ANCA titers in AAV supports a role for B-cells in the pathogenesis of the disease [166, 167]. Such B-cells appear to be able to evade the regulatory processes that ensure tolerance to self-proteins. For example, autoreactive B-cells may persist due to low surface expression of CD19, resulting in decreased signaling strength and thus allowing them to evade normal tolerance mechanisms [168].

Further work has examined the role of regulatory B-cells (Breg) in AAV [169], although this is made challenging by the absence of a definitive Breg phenotype [170]. The CD19+CD24(hi)CD38(hi) B-cell is one subset that has been demonstrated to possess regulatory potential [171]. AAV patients with active disease were observed to have significantly lower proportions of CD19+CD24(hi)CD38(hi) B-cells than healthy controls, and B-cells from such patients produced less IL-10 when stimulated *in vitro* [169]. Both the CD19+CD24(hi)CD38(hi) and IL-10+ B-cell populations increased as patients transitioned from active disease to remission [169]. Taken together, these findings suggest that active AAV is associated with deficits in regulatory B-cells.

The selection and maturation of B cells that produce anti-PR3 ANCA may occur in sites of early granulomatous inflammation as histological examination of granulomata in GPA show B-cell clusters closely associated with numerous PR3-positive cells [165]. The proteasome inhibitor bortezomib was studied in a murine model of AAV, noting that bortezomib treatment was associated with MPO-specific plasma cell depletion, reduced anti-MPO titers, and prevention of crescentic GN [172]. One case of refractory MPA successfully treated with bortezomib was recently reported [173]. However, further investigation into timing of treatment and adverse effect profile is needed before bortezomib can be recommended as a routine treatment for refractory AAV.

Complement-Mediated Mechanisms

The presence of immune complex deposits in skin tissue of patients with cutaneous vasculitic lesions, and in renal biopsy tissue in those with ANCA-associated crescentic glomerulonephritis, suggests a role for complement-mediated immune mechanisms in development of inflammation and glomerular damage in AAV [174]. Chen and colleagues [175] demonstrated that approximately 33% of renal biopsy samples from patients with ANCA-associated NCGN demonstrated C3c expression. Membrane attack complex (MAC),

along with C3d and factors B and P were found in glomeruli and microvasculature of human renal biopsy tissue [176]. Xiao and colleagues [177] employed renal biopsy samples from patients with MPO-ANCA-associated pauci-immune NCGN to study the various complement components. All biopsy samples showed MAC, factor B and C3d. Diseased glomeruli were found to express C3d and factor B that co-localized with expression of MAC. This, coupled with the observation that C4d was not detected in either frozen renal sections or paraffin-fixed sections, strongly suggested that the renal damage associated with AAV was secondary to the alternative pathway of the complement system [176]. In addition, complement deposition has been associated with more severe renal disease [175].

Multiple retrospective studies have demonstrated an association between hypo-complementemia at AAV onset, likely reflecting systemic activation of the complement cascade, and poor outcomes [178-180]. In the largest of these studies, low serum C3 at disease onset was an independent predictor of end-stage renal disease and death [179].

In vitro studies indicate that C5a, acting via the neutrophil C5a receptor (C5aR), plays a role in priming neutrophils for ANCA activation via the alternative pathway [181]. This suggests that an amplification loop, comprising C5a and neutrophil C5aR, might mediate ANCA-induced neutrophil activation [181, 182].

Additionally, there is evidence that regulation of the alternative pathway is impaired in AAV. Complement factor H, a negative regulator of the alternative pathway, was detected at significantly lower levels in patients with active MPO-AAV compared to patients in remission and healthy controls [183]. Furthermore, patients with active AAV exhibited deficient factor H function, shown by reduced regulation of C3b and impaired protection of erythrocytes against plasma-mediated lysis [184]. These data reinforce the role of the alternative pathway in AAV, and suggest that impaired negative regulation of this pathway could play a role in its pathogenesis. It is not yet understood what mechanisms underlie this dysregulation.

Perhaps the most convincing evidence of the role of the complement comes from animal models where the development of vasculitis is completely blocked by complement depletion [185]. Xiao and co-workers [182] studied the role of specific complement activation pathways in the development of NCGN and vasculitis using wild type and knockout mice for the common pathway component C5, the classic and lectin binding pathway component C4, and the alternative pathway component Factor B. They showed that C5^{-/-} and Factor B^{-/-} mice, but not C4^{-/-} mice, were protected from disease development after injection of anti-MPO IgG. Their findings suggested that stimulation of neutrophils by ANCA caused release of factors that activate complement via the alternative pathway, initiating an inflammatory amplification loop that mediated severe necrotizing inflammation. Inhibition of complement factor C5 protected against anti-MPO IgG-mediated NCGN, with an 80% reduction in glomerular crescent formation when anti-C5 monoclonal antibodies were administered one day after disease induction [185].

The use of C5 inhibition to treat AAV has also been tested in patients. In a recent randomized controlled trial, C5a receptor inhibitor avacopan was non-inferior to high-dose prednisolone in achieving clinical response in active vasculitis treated with cyclophosphamide or rituximab [186]. In addition to providing a possible means of reducing glucocorticoid exposure, this trial provides further evidence for the role of complement in AAV.

CONCLUSION

The AAV comprising GPA, MPA and RLV are life-threatening diseases affecting small to medium sized vessels with significant overlap in their non-organ specific and organ specific features. Current diagnosis of AAV relies on recognition of a clinical picture and supporting evidence from radiological, immunological and histological investigations. Their highly variable clinical presentation and absence of diagnostic criteria often leads to a delay in diagnosis and initiation of effective therapy. The pathogenesis of AAV is complex, involving both the innate and adaptive immune systems. Significant advances have been made in understanding the AAV over the past few decades, notably with development of animal models. Future development of effective treatment approaches and preventative strategies will be targeted based on improving understanding of pathogenic mechanisms in AAV.

ABSTRACT

Cryoglobulinemic vasculitis, also termed mixed cryoglobulinemia syndrome, is a rare systemic small vessel vasculitis due to the vessel deposition of immune-complexes, mainly mixed IgG-IgM cryoglobulins. In the majority of cases, it is associated with the hepatitis C virus infection, immunological, and neoplastic diseases. Cryoglobulinemic vasculitis is characterized by the classical triad of purpura, weakness, and arthralgia, frequent multiple organ involvement, and with infrequent late lymphatic and hepatic malignancies. The etiopathogenesis of cryoglobulinemic vasculitis is not completely understood. However, hepatitis C viral infection and associated lymphotropism, genetic, and environmental factors play important roles in B-lymphocyte expansion and cryoglobulin and immune-complex production. The diagnosis is suggested by clinical evidence of purpura, circulating mixed cryoglobulinemia and low C4 levels, and pathologically evident leukocytoclastic vasculitis in skin biopsy lesions. The prognosis is poor in patients with renal disease, liver failure, malignancy, and/or widespread vasculitis with multiple organ involvement. Treatment is directed toward eradicating hepatitis C infection employing the new direct-acting antivirals, immunomodulatory, and immunosuppressant medications as warranted by the level of clinical severity.

INTRODUCTION

Cryoglobulinemic vasculitis (CV) is a small vessel vasculitis (SVV) due to the vascular deposition of cryoprecipitable and/or non-cryoprecipitable immune-complexes (IC) and complement [1]. Cryoglobulinemia and cryoimmunoglobulinemia are interchangeable terms

that refer to the presence in the serum of one (monoclonal cryoglobulinemia) or more immunoglobulins (Ig) or mixed cryoglobulinemia (MC), which precipitate at temperatures below 37°C and re-dissolve on rewarming [1].

NOSOLOGY AND CLASSIFICATION

Cryoglobulinemia is classified into three categories according to the Ig composition [1]. Type I cryoglobulinemia consists of singular isotypes or subclass of Ig, whereas types II and III MC contain ICs composed respectively of polyclonal IgG autoantigens and monoclonal or polyclonal IgM autoantibodies, the latter of which contain rheumatoid factor (RF) activity. Type II MC shows a microheterogeneous composition with immunoblotting and two-dimensional polyacrylamide gel electrophoresis of oligoclonal IgM or a mixture of polyclonal and monoclonal IgM [1-4]. This serological subset represents an intermediate evolutionary state between type III and type II MC, so termed type II-III MC. These findings are in agreement with molecular studies that show the presence of oligoclonal B-lymphocyte proliferation in liver and bone marrow tissue from patients with MC [1-6]. Whereas cryoglobulinemia type I is often asymptomatic and usually associated with well-known hematological disorders [1-6], MC occurs in diverse infectious and systemic disorders and frequently presents as an isolated laboratory finding without clinical significance. Mixed cryoglobulinemia syndrome (MCs) and CV are interchangeable terms for the resultant distinctive SVV related to cryoglobulinemia [1-6].

EPIDEMIOLOGY

Cryoglobulinemic vasculitis is a rare disorder of yet certain prevalence with marked heterogeneity in its geographical distribution, and increased prevalence in Southern more than Northern Europe or Northern America. The male to female ratio is 3:1, with the most common age at onset of disease in the fourth to fifth decades and in older age [1-5]. Because of the clinical polymorphisms of CV the prevalence of single manifestation such as skin vasculitis, nephritis, chronic hepatitis, and peripheral neuropathy vary largely among cohorts. The relationship between hepatitis C virus (HCV) with cryoglobulinemia and CV has been examined in numerous cohorts [1, 4, 5]. Low levels of circulating MC are detectable in more than 50% of patients while overt CV develops in approximately 5% of HCV-infected individuals [1, 8]. Considering the high prevalence of HCV infection worldwide, an increasing number of patients with HCV-related CV and extrahepatic manifestations are expected to occur particularly in underdeveloped countries where HCV prevalence is increased relative to the general population [1, 4]. Essential MCs (EMCs) and CV, so defined as the absence of a recognized triggering factor that underlie a systemic infectious or specific neoplastic disorder, occur less frequently in individuals of Southern European descent and in selected geographic areas where there is a higher prevalence of HCV infection and CV [1, 4].

ETIOPATHOGENESIS

The triggering factors and etiopathogenesis of CV and MCs are depicted in Figures 1 and 2. Vascular deposition of circulating IC, cryoglobulins and complement mediated by humoral and local factors, affects small vessels, predominantly arterioles, capillaries, and venules similar to Henoch-Schonlein purpura, another IC type of SVV, with variable systemic organ involvement [1-5]. Mild to moderate chronic hepatitis is related in up to two-thirds of affected patients with CV suggesting a pathogenic role for hepatotropic viruses [1-4, 9].

Hepatitis B virus (HBV) is a possible causative factor in <5% of patients, while HCV is considered the main pathogenic agent in CV [1, 4, 5]. First proposed by two independent groups who recognized the increased prevalence of serum anti-HCV antibodies in CV patients relative to the general population [10, 11], the causative link between HCV and CV was later established when the presence of HCV RNA was detected by polymerase chain reaction (PCR) in 86% of patients with CV [7]. The causative role of HCV in CV is apparent in up to 95% of patients among cohorts of diverse geographical derivation [1, 4-6, 9]. In consideration of the striking association of HCV with CV, EMC occurs in a minority of patients [1, 4]. The clinical features and prognosis of CV are linked to the natural history of chronic HCV infection with different CV phenotypes believed to be the result of contributory genetic and environmental cofactors which hitherto remain unknown [1, 4, 12]. The role of HCV in autoimmunity has been ascribed to viral lymphotropism [1, 4, 5, 12] wherein the HCV, which lacks the ability to integrate into the host genome due to absence of reverse transcriptase activity, chronically stimulates the immune system leading to autoimmune phenomena. The proposed etiopathogenesis (Figure 2) is connected to HCV-related epitopes, autoantigens, and molecular mimicry-related mechanisms such as the association with the anti-GOR autoantibody, as well as the binding of HCV to host low-density lipoprotein (LDL), specific antiviral IgG and IgM, RF and cryoglobulins, and monoclonal RF bearing B-cells that express the WA cross-idiotype. Collectively, these immunological phenomena are the cause and the consequence of chronic stimulation of B-lymphocytes with expansion of B-cell subpopulations. HCV-related lymphomagenesis represents an important model of virus-driven malignancy, similarly to that observed for mucosa-associated lymphoid tissue (MALT) lymphoma of the stomach related to gastrointestinal *Helicobacter (H.) pylori* infection [1, 4, 12], two malignancies characterized by an analogous multistep and multifactorial etiopathogenesis.

The interaction between the HCV E2 envelope protein and CD81 molecule, a ubiquitous tetraspannin present on the surface of B cells, likely represents an important pathogenic step in the development of HCV-related autoimmune and lymphoproliferative disorders that results in potent sustained polyclonal stimulation of the B-lymphocytes [1, 4, 12]. The occurrence of HCV-related autoimmune-lymphoproliferative disorders may also be related to t(14;18) translocations found in B-cells of HCV-infected patients leading to increased expression of the Bcl-2 protein, with inhibition of apoptosis and abnormally prolonged B-cell survival [1, 4, 12, 13]. Apart from cryoglobulin production with or without overt CV, HCV-driven lymphoproliferation could explain the pathogenic role of HCV infection in idiopathic B cell lymphoma [1, 4]. Since the first description in 1994 [14], epidemiological and laboratory studies have confirmed this association in geographical areas where both HCV-associated CV and lymphoproliferative disorders occur [1, 4, 12].

Abbreviations: MC, mixed cryoglobulinemia; MCs, mixed cryoglobulinemia syndrome; ALD, autoimmune-lymphoproliferative disorders, HCV, hepatitis C virus; HBV, hepatitis B virus.

Figure 1. The different clinical and virological subsets of MCs can be schematically summarized as follows: (1) Essential MC; (2) Essential MC and HCV-related MC as an overlapping syndrome (lymphoproliferative disorders, Sjögren syndrome, rheumatoid arthritis, autoimmune hepatitis, and B-cell lymphomas); (3) Subsets of HCV-associated MC; and (4) MC associated with other infectious agents notably hepatitis-B virus.

Abbreviations: HCV, hepatitis C virus; RF, rheumatoid factor; IC, immune-complex; pSS, primary Sjögren syndrome; SS, sicca syndrome; PCT, porphyria cutanea tarda; HCC, hepatocellular carcinoma; B-NHL, B-cell non-Hodgkin lymphoma; CPX, cyclophosphamide; RTX, rituximab; LAC, low antigen-content.

Figure 2. Left: CV is the most frequent extrahepatic manifestation of the so-called HCV syndrome. CV represents a crossing road between benign and malignant HCV-related complications. Given its biological characteristics, HCV may be involved in a wide number of autoimmune and lymphoproliferative disorders. This figure summarizes the main causative factors including, infection, toxics, genetic and environmental causes potentially involved in the pathogenesis of the complex HCV syndrome, in particular of CV. These factors, alone or in combination, may trigger two nonexclusive multistep pathogenic processes, notably the production of benign poly-oligoclonal B-cell proliferation responsible for organ- and non-organ-specific autoimmune disorders including IC-mediated CV; and another characterized by different oncogenic alterations, which ultimately leads to malignant complications. Right: Therapeutic strategies in patients with HCV-related CV and other autoimmune lymphoproliferative disorders. Following the multistep pathological process leading from HCV infection to overt CV, etiologic, pathogenic and symptomatic treatments are instituted at different levels.

The etiopathogenesis of HCV-negative CV [15] remains a challenge to explain apart from concurrent infectious processes including HBV and concomitant autoimmune rheumatologic and lymphoproliferative disorders (Figure 1). Patients with human immunodeficiency virus (HIV) type I infection may also have HCV co-infection. HIV may exert continuous antigenic stimulation of B-cells leading to MC type III production early in its course, followed by monoclonal type II MC, and the typical manifestations of CV [1-4, 12].

CLINICAL MANIFESTATIONS

The demographic, clinical-serologic and virologic findings of 270 patients with CV at our institution are shown in Table 1. The triad of purpura, weakness and arthralgia, the clinical hallmark of CV and MCs, were frequent seen in addition to chronic hepatitis, type 1 membranoproliferative glomerulonephritis (MPGN), peripheral neuropathy, skin ulcers, diffuse vasculitis, and in some instances, malignant B-cell non-Hodgkin lymphoma (B-NHL) and hepatocellular carcinoma [1-5, 9, 12]. Although the prevalence of singular clinical-serological features of CV in our cohort was comparable among those with type II and III MC, the reported clinical variability may relate to bias of ascertainment from renal or rheumatology clinics, and cohorts of geographically diverse origin [1-5, 8].

There are different presenting clinical-serological patterns that vary from mild arthralgia and sporadic purpura in those with MC alone, to more severe cutaneous and systemic involvement of classical MCs [1-4]. In all such patients, the disease combines MC with RF activity, low C4 levels, and the clinical-pathological features of orthostatic purpura due to leukocytoclastic vasculitis (LCV) with variable multi-organ involvement. Patients chronically infected with HCV demonstrate asymptomatic serum MC that may precede the clinical onset of disease by years to decades [1, 4]. Conversely, some patients show typical cryoglobulinemic manifestations without serum cryoglobulins. The absence of this serological hallmark is not surprising since cryoglobulins represent only a portion of IC that cryoprecipitate, which may be transient and vary both among patients and during follow-up in individual patients [1, 4]. Most experts agree that repeated cryoglobulin determinations are necessary for a definite diagnosis in such patients.

Cutaneous manifestations are the most common clinical feature of CV, with orthostatic purpura, the pathognomonic feature, varying largely in dimension and diffusion to sporadic isolated petechiae and severe vasculitic lesions, and complicated by torpid ulcers of the legs and malleoli [16]. Repeated episodes of purpura lead to stable, sock-like ochraceous discoloration of the legs [1, 4]. Humoral cofactors and vascular disturbances stemming from increased cryocrit levels, chronic venous insufficiency and physical stress all contribute to vasculitic alterations. More intense purpuric manifestations may occur in the afternoon with prolonged standing and when cryocrit levels are highest, especially in muggy weather conditions. Arthralgia, non-erosive oligoarthritis, and less frequently frank arthritis may also be noted. When CV occurs in association with the sicca syndrome, there was mild xerostomia and xerophthalmia in up to one-half of patients [1, 4].

Table 1. Cryoglobulinemic vasculitis: Demographic, clinicoserological, and virological findings at a single institution*

Total Number of Patients	270
Mean age at disease-onset ($\pm$ SD), years (range)	55 ($\pm$ 14) (29-74)
Female/Male ratio	3:1
Disease duration, mean $\pm$ SD years (range)	14 ($\pm$ 11) (2-42)
Purpura	98%
Weakness	98%
Arthralgia	93%
Non-erosive arthritis	9%
Raynauds phenomenon	32%
Sicca syndrome	51%
Peripheral neuropathy	81%
Renal involvement	32%
Liver involvement	73%
B-cell non-Hodgkin lymphoma	12%
Hepatocellular carcinoma	3%
Mean cryocrit% ($\pm$ SD)	4.1 ($\pm$ 14)
Type II/type III mixed cryoglobulins	2/1
Mean C3 ($\pm$ SD) in mg/dl (normal 60-130)	91 ($\pm$ 35)
Mean C4 ($\pm$ SD) in mg/dl (normal 20-55)	10 ($\pm$ 14)
Antinuclear antibodies	31%
Antimitochondrial antibodies	9%
Anti-smooth muscle antibodies	15%
Anti-extractable nuclear antigen antibodies	9%
Anti-HCV RNA	92%
Anti-HBV antibodies	30%
HBsAg	1%

*Evaluated at the end of the patient follow-up period.

Peripheral nervous system involvement that includes small fiber neuropathy of the legs with painful, burning paresthesia that worsens at night is often resistant to treatment. A minority of patients develop large fiber sensorimotor involvement, but when present, most often occurs with abrupt asymmetric onset of mononeuritis. Peripheral neuropathy may also be triggered or exacerbated during the first several weeks of treatment with interferon-alpha (IFN- α) in patients so disposed [1, 4]. Central nervous system vasculitis, albeit rare, presents with focal deficits such as dysarthria and hemiplegia, which may be difficult to distinguish from more common atherosclerotic vascular sequela.

Systemic liver involvement is rarely observed in other systemic vasculitides, but is present in CV, and generally preceded by mild to moderate chronic hepatitis that is apparent at presentation or develops in two-thirds of patients particularly those with HCV-related CV [1, 4]. Clinically overt liver cirrhosis occurs in one-quarter of patients, while life-threatening hepatorenal syndrome occurs in association with progressive CV [9]. The overall outcome of CV-associated chronic hepatitis seems to be more favorable than HCV-related hepatitis without MCs, whereas hepatocellular carcinoma is less frequently observed in HCV-related CV compared to the overall population of HCV-infected individuals. Such differences are difficult to fully explain, however, the relatively low prevalence of the 1b HCV genotype in those that develop CV, along with a lower median consumption of alcohol might predict a

more benign clinical course of liver involvement [1, 4]. Immune complex-mediated glomerulonephritis, most often seen in type 1 MPGN, affects the prognosis and survival of patients with CV due to hypothesized immune mechanisms [1, 4]. Intestinal vasculitis presents with severe life-threatening acute abdominal pain necessitating prompt diagnosis and aggressive treatment [1, 4].

Interstitial lung disease characterized by subclinical alveolitis has been described in those with CV and in association with isolated HCV infection [1, 4]. When present, interstitial lung disease can be a predisposing condition to pulmonary infections, and in rare instances, to clinically manifest interstitial lung fibrosis. Capillaritis complicated by severe cough and hemoptysis, are other rare manifestations of CV-related lung involvement, as well as overt hyperviscosity syndrome are due to high levels of serum cryoglobulins [1, 4].

A low or undetectable C4 level with a normal C3 fraction occurs in patients with CV regardless of disease activity. *In vitro* consumption of hemolytic complement is due to the anti-complement activity of cryo-Ig [1, 4]. A sudden increase in C4 from low to abnormally high levels can precede the development of B-NHL [1]. The absence of a clear-cut correlation between the severity/activity of CV clinical manifestations and the observed cryocrit levels may be related to the large variability of cryo- and non-cryoprecipitable IC ratio and/or the intrinsic ability of IC to activate complement, as well as the possible *in situ* formation of IC [1].

Endocrine disorders occur more frequently in CV than in the general population including thyroid disturbances, type II diabetes mellitus, and gonadal dysfunction [1, 12, 17]. The former include autoimmune thyroiditis, subclinical hypothyroidism, and rarely thyroid cancer. Reversible hyperthyroidism occurs as a complication of IFN- α treatment [1].

B-NHL, the most common malignancy in association with CV, is often seen late in the course of MCs [1, 4, 12]. The development of B-NHL may be a consequence of peripheral B-cell expansion of lymphoid infiltrates in the liver and bone marrow. Such lymphoid infiltrates, which are considered to be early indolent lymphomas, are indistinguishable from more advanced B-cell cancers that include chronic lymphocytic leukemia, small lymphocytic lymphoma, and immunocytoma [1, 4, 12]. While the majority of affected patients remain stable for years, overt B-NHL is observed in approximately 10% of affected patients most often late in the course of CV [1, 4-6, 12]. Other neoplastic manifestations, including hepatocellular carcinoma and papillary thyroid cancer occur in the natural progression of CV [1, 4, 12]. Accordingly, MC may be considered, in part, a pre-neoplastic disorder in which careful clinical monitoring is recommended even when the severity of MCs is mild.

DIAGNOSIS

There are no standardized methodologies for the measurement of cryoglobulin levels [1, 4] nor have the diagnostic criteria for CV been prospectively validated. In 1966, Meltzer and Franklin [2] described EMCs in patients with the triad of purpura, weakness, and arthralgia, circulating MC, low C4 levels, LCV of arterioles, capillaries and venules, and multiorgan involvement without discernible infectious, autoimmune, or systemic involvement [1-6]. Recent classification criteria for CV were developed by a cooperative multicenter study using a standardized methodology [18]. Successively validated in MC patients referred to experts

from a larger number of countries, these criteria may be usefully employed in epidemiological and clinical-pathogenic studies, and prospective therapeutic trials [19]. Evidence of MC in the serum of patients with suspected CV is necessary for a definite classification of the disease [18, 19], taking into account the above-mentioned variability of IC cryoprecipitation needing repeated cryoglobulin determinations [1].

DIFFERENTIAL DIAGNOSIS

Figure 3 describes aspects of the differential diagnosis of CV which shares a number of etiopathogenic events with both HCV-related and idiopathic disorders, namely sicca syndrome, primary Sjögren syndrome (pSS), polyarthritis, classical rheumatoid arthritis, autoimmune hepatitis, and B-NHL [1, 4, 12]. Therefore, a differential diagnosis with regard to the presence or absence of HCV infection should be carefully made in all patients with cryoglobulinemia and/or some autoimmune/neoplastic manifestations; a correct disease classification may decisively affect the overall clinical therapeutic approach and outcome. The presence of HCV in the large majority of individuals with CV may nonetheless lead to difficulty in the differentiation of CV from HCV-infected patients with other extrahepatic manifestations that characterize the HCV syndrome [12, 20]. Such patients develop slow progression from mild HCV-associated hepatitis to various extrahepatic manifestations including arthralgia, RF-positive arthritis, sicca syndrome, Raynaud's phenomenon, and others to clinically overt cryoglobulinemic syndrome (Figure 2). Of note, a minority of patients with long-lasting CV develop a clinically relevant malignancy [1, 20].

Patients with mild CV complain of arthralgia often without synovitis [1, 4, 21, 27] while those with HCV-associated CV and symmetrical erosive polyarthritis are more likely to have the syndrome of overlapping CV-rheumatoid arthritis further definable by serum anti-cyclic citrullinated peptide (anti-CCP) IgG antibodies and RF serology (Figure 3). Sicca syndrome occurs in up to one-half of patients with CV; however, formal criteria are satisfied in only a minority of patients [1, 4, 12, 21]. Patients with pSS shares various symptoms with CV including purpura, xerostomia, xerophthalmia, arthralgia, and laboratory evidence of RF seropositivity, cryoglobulinemia, and the associated complication of B-cell lymphoma [21]. Histopathological alteration of the salivary glands and the specific autoantibody pattern (anti-Ro/SSA-La/SSB) of pSS are rarely found in patients with MCs. Moreover, pSS is rarely complicated by chronic hepatitis, glomerulonephritis, or concomitant HCV infection. In this regard, HCV infection should be considered an exclusionary criterion for pSS [21]. In rare cases, and often in subjects without HCV infection, the differential diagnosis may be challenging. In those instances, it may be more appropriate to classify such patients as CV-pSS overlap syndrome [1, 4, 12, 21]. This clinical condition shows a rather severe clinical progression, less frequent Ro/SSA and La/SSB seropositivity, high levels of serum MC, hypocomplementemia, with frequent autoimmune-vasculitic manifestations, and a higher risk of lymphoma [4, 21, 27].

Autoimmune hepatitis may be associated with HCV infection in the same geographic areas that HCV-associated CV occur. The differential diagnosis between CV and autoimmune hepatitis may be difficult due to the presence of hepatic and extrahepatic autoimmune phenomena in both entities [1, 4, 12]. The presence of the typical features of CV including

LCV, hypocomplementemia, glomerulonephritis, but generally mild hepatitis may collectively be a clue in differentiating CV from classical autoimmune hepatitis [1, 4, 12].

Abbreviations: CV, cryoglobulinemic vasculitis; RF, rheumatoid factor; CCP, cyclic citrullinated peptide; pSS, primary Sjogren syndrome; LCV, leukocytoclastic vasculitis; B-NHL, B-cell non-Hodgkin's lymphoma; RA, rheumatoid arthritis.

Figure 3. Differential diagnosis of CV and other rheumatic diseases. In clinical practice, it is possible to observe some clinical overlap syndromes involving CV and other autoimmune lymphoproliferative disorders. In particular, pSS and RA may share some clinico-pathological features with CV, including a possible association with HCV infection. However, a correct differential diagnosis may be done based on some considerations: pSS shows a typical histopathological pattern of salivary gland involvement and specific autoantibodies anti-Ro (SSA) and La (SSB), which are rarely found in patients with CV. Conversely, cutaneous LCV, visceral organ involvement including glomerulonephritis, hepatitis, low C4 and HCV infection, are typically found in CV. On the other hand, erosive symmetrical polyarthritis and serum anti-CCP characterize classic RA. Moreover, B-NHL may complicate CV, pSS, and RA. B-NHL may be suspected after careful clinical-serological monitoring. Finally, incomplete variants of both pSS and RA, namely isolated sicca syndrome and arthritis, can be associated to CV in the setting of chronic HCV infection, but they do not generally present typical clinical-serological and pathological features of pSS or RA.

PROGNOSIS

The overall 10-year survival of CV is estimated to be about 50% [9]. The clinical course and prognosis of CV relates mainly to disease manifestations, response to treatments and comorbid disorders, as well as, complications accrued to CV and its treatment [9]. Those with renal disease, liver failure, lymphoproliferative and other malignancies demonstrate the least favorable outcome [1, 4, 9, 12]. Careful monitoring of patients to avoid life-threatening complications of CV, including nephropathy, widespread systemic vasculitis, hepatitis, and malignancy, favor a better prognosis.

TREATMENT

Figure 4 summarizes the therapeutic approach to CV. Taking into account three important aspects of disease pathogenesis, the treatment can be aimed at chronic immune stimulation by eradicating HCV infection, attenuating the resultant T- and B-cell activation, and attenuating the production of cryoglobulins and IC, as well as, the identification and treatment of B-cell lymphoproliferation to avert the development of B-NHL. This multistep, multifactorial etiopathogenesis-oriented approach to therapy targets HCV infection, B-cell proliferation, and the resultant CV inflammatory involvement. The recent introduction of direct acting antivirals (DAAs) led to sustained clearance of HCV in the large majority of patients so treated [4, 22-27], without the frequent side-effects previously observed with IFN- α treatment, such as peripheral neuropathy, thyroiditis, and rheumatoid-like polyarthritis [1, 4, 12]. Preliminary studies suggest a role for DAAs in the treatment and eradication of HCV, whereby elevated its tolerability and efficacy, offers new hope in the management of severe complications [22-27]. However, the variable and unpredictable CV response to the antiviral therapy observed in some patients, including the paradoxical response with disease exacerbation or new symptom appearance, indicates that DAAs effect on CV needs to be further evaluated. The immune system of a single patient may be decisive in the clinical outcome following antiviral treatment. There is a point of no return in a viral-driven lymphoproliferative disorder that may affect the overall clinical response after HCV eradication. Like *H. pylori*-associated gastric lymphomas [1, 4], HCV-associated CV is more responsive to biologically based treatment of the underlying infection, early in the he early phase of the illness.

Therapeutic Strategies of Cryoglobulinemic Vasculitis (CV)		
Activity Levels	Treatment Strategies	Symptom Combination & Treatments
asymptomatic	monitoring (DAAs for HCV eradication)	CV with severe-active manifestations GN, SU, s-m neuropathy, diffuse vasculitis
mild-moderate purpura, weakness, arthralgia, mild sensory neuropathy	low-medium dose CS +/- LAC- β et +/- other symptomatic DAAs	
moderate-severe active chronic hepatitis, glomerulonephritis, skin vasculitis	DAAs low-medium dose CS +/- RTX	CV with active chronic hepatitis + minor MCs symptoms
severe-rapidly progressive GN, s-m neuropathy, Diffuse vasculitis	PE, CS, and CPX (or RTX) DAAs	sequential (or combined) treatment DAAs $\rightarrow$ Rituximab

Abbreviations: HCV, hepatitis C virus; CS, corticosteroids; LAC, low-antigen-content; DAAs: direct-acting antivirals; CPX, cyclophosphamide; RTX, rituximab; MCs, mixed cryoglobulinemic syndrome; GN: glomerulonephritis; s-m-neuropathy: sensory-motor neuropathy; SU: skin ulcers

Figure 4. Therapeutic strategy of cryoglobulinemic vasculitis according to the activity and severity of the disease or symptom combination. Asymptomatic generally require careful monitoring. Those with mild manifestations such as transient purpuric lesions of the legs may be monitored and offered therapy to eradicate HCV infection. Individuals with moderate to severe manifestations, mainly active chronic hepatitis are treated with new direct-acting antiviral therapies. Patients with severe, rapidly progressive disease complications or a partial response to traditional therapy receive aggressive treatment regimens similar to other systemic vasculitides; employing, sequential or combined treatment schedules.

Physicians must choose from among available therapies for CV including low-antigen-content (LAC) diets, plasma exchange (PE), and immunosuppressant regimens employing corticosteroids, rituximab, and cyclophosphamide alone or in combination depending upon the severity and activity of the illness and clinical manifestations [1, 4, 17]. A LAC-diet improves the clearance of circulating IC by restoring the activity of the reticuloendothelial system, which becomes overloaded, by circulating cryoglobulins [1, 4, 21]. It reduces the input of alimentary macromolecules crossing the mucosal barrier of the gut as some foods such as dairy products and eggs present a potential antigenic activity and might otherwise be pathogenic. Reduction of the alimentary input of macromolecules directed to mononuclear phagocytic system improves its function in conditions characterized by abnormal endogenous hyperproduction of IC responsible for organ damage such as MCs. Combined LAC-diet and 2 to 4 mg per day of 6-methyl-prednisolone may be sufficient to ameliorate mild manifestations of CV such as sporadic purpura and arthralgia. The limitations of an LAC-diet treatment include poor patient compliance, which can be improved by tailoring the treatment duration, for example 7 to 14 days of restricted diet followed by 14 to 28 days of free diet. Those with mild-moderate symptoms including palpable purpura may be particularly sensitive to the small variations in daily steroid dosage of 1 to 2 mg, and derive benefit from dietary therapy.

Cyclophosphamide and in particular, rituximab are each first-line therapies for EMCs [1, 4, 21, 22]. Rituximab is first-choice treatment based on the results of observational and controlled studies in seronegative and seropositive HCV patients with CV [1, 4, 21, 22, 27-31]. Traditional and double-filtration PE can reduce the levels of circulating IC and cryoglobulins [1, 4, 21]. Oral cyclophosphamide at the dose of 50 to 100 mg per day for 2 to 6 weeks during the tapering of PE sessions, as well as rituximab, reinforces the beneficial effects of PE. Moreover, the latter can also potentiate the effect of cyclophosphamide [9], and is beneficial in the treatment of fulminant manifestations of CV such as widespread vasculitis and/or rapidly progressive MPGN [9].

The treatment of CV should be tailored to individual patients according to the severity of clinical symptoms, with the most severe vasculitic manifestations treated promptly with combination corticosteroids, PE, and cyclophosphamide or rituximab [1, 4, 9, 21]. Pilot studies suggest that sequential or combined antiviral and immunosuppressive treatment is a useful strategy [4, 27, 30, 31] especially in those with major clinical manifestations and partial or transitory remission after antiviral therapy (Figure 4). Clinically asymptomatic patients may be monitored without treatment even in the presence of elevated cryocrit levels; in these patients, an attempt to HCV eradication should be always considered. Careful clinical monitoring of the disease is mandatory in all cases with particular attention to neoplastic transformation [1, 4].

CONCLUSION

Cryoglobulinemic vasculitis is an important model for the study of autoimmune and lymphoproliferative diseases mediated by viral infections. Recent advancements in the understanding of the underlying multifactorial and multistep processes in the etiopathogenesis of CV have translated into more effective etiological treatment modalities including antiviral treatments directed at eradication of HCV infection as both a triggering factor and contributor

to the self-perpetuating mechanism of autoimmune disease. In addition, pathogenetic therapies may be employed to target the variably severe consequences of LCV, systemic SVV, multiorgan involvement, and malignancies. Future challenges in CV include improvements in the differential diagnosis with some overlapping disorders, as well as the improvement in therapeutic strategies tailored to different CV clinical variants in selected patients.

Chapter 205

AORTITIS AND PERIAORTITIS

***Eugenia Accorsi Buttini, MD, Chiara Marvisi, MD
and Augusto Vaglio*, MD, PhD***

Nephrology Unit, Parma University Hospital, Parma, Italy

ABSTRACT

Aortitis and periaortitis are inflammatory diseases of the aorta and its branches. They differ in the extension of inflammation, which is confined to the aortic wall in aortitis and extends in the periaortic space in periaortitis. Although aortitis occurs as either an infectious or a non-infectious process, the latter suggests an etiology related to large-vessel vasculitis. Periaortitis and aortitis are recognizable fibro-inflammatory systemic disorders, categorized under the rubric of IgG4-related diseases. This chapter reviews the nosology, pathogenesis, histopathology and clinical phenotype of the different forms of aortitis and periaortitis, and discusses their diagnosis and management.

Keywords: aortitis, periaortitis, IgG4-related disease, fibrosis, vasculitis, giant cell arteritis, Takayasu arteritis

INTRODUCTION

Aortitis and periaortitis are in the spectrum of systemic inflammatory disorders characterized by chronic inflammation that may be limited to the aortic wall or to the adjacent periaortic space. Both conditions may arise in the context of a recently recognized clinical-pathological entity known as an IgG4-related disease (IgG4-RD), characterized by marked fibrosis and T-lymphocyte and IgG4-positive plasma cell infiltration of various organs.

In 2015, a standardized classification for inflammatory diseases of the aorta was proposed as a part of a consensus statement issued by the Society for Cardiovascular Pathology and the Association for European Cardiovascular Pathology [1]. The committee identified three general categories of inflammatory aortic disease: (a) atherosclerosis, (b) atherosclerosis with excessive inflammation and (c) aortitis/periaortitis.

Atherosclerosis is a degenerative inflammatory process that starts from the intimal layer of arteries. It is classified as mild, moderate, or severe based on the medial destruction and the presence of extracellular lipid deposition with fibrosis. In some cases, the inflammatory reaction is unusually intense but always due to atherosclerosis. Two major examples of this phenomenon are atherosclerosis with excessive neutrophilic inflammation and inflammatory abdominal aortic aneurysms (IAAA).

The terms aortitis and periaortitis are reserved for inflammatory aortic conditions unattributed to atherosclerosis alone. Aortitis is a pathological term that describes an extensive inflammatory process that involves the media and/or the intima of the aortic wall.² The inflammatory response affects the aorta at any level and extends to its major branches and other large vessels. Aortitis can be the presenting feature of large vessel vasculitides (LLV), but may also occur in the absence of clinical symptoms or signs of systemic vasculitis making it an incidental diagnosis on imaging studies or in histologically studied specimens of surgically resected aortic tissue [1]. Aortitis rarely develops in association with concomitant rheumatologic disorders or in the presence of an infectious illness.

It is recommended to apply the term periaortitis to an inflammatory process that arises from the adventitia of the aortic wall and extends into the surrounding periaortic space. The ensuing pathological lesion consists of a fibrous component and a chronic inflammatory infiltrate. Periaortitis typically involves mainly the lower abdominal aorta and the common iliac arteries and can arise around either a dilated or non-dilated aorta. The tissue infiltrating the retroperitoneum frequently encases adjacent structures such as the ureters and the inferior vena cava [3]. Originally, periaortitis was thought to be confined to the abdominal aorta, although histopathologic studies provided evidence of simultaneous involvement of other vascular districts [4]. Computed tomography (CT), magnetic resonance imaging (MRI) and especially ^{18}F -fluorodeoxyglucose positron emission tomography (^{18}F -FDG-PET) imaging identify vascular inflammation in virtually all large arteries. The thoracic aorta and the epiaortic arteries are involved in about a third of patients suffering from abdominal periaortitis wherein the condition is typically asymptomatic [5]. The coronary, renal, mesenteric and coeliac arteries may rarely be involved. While diverse causes of periaortitis and aortitis may be clearly distinguishable, the differential diagnosis is often challenging when an affected patient presents with nonspecific systemic symptoms or fever of unknown origin, and the inflammatory process diffusely involves the aorta.

In 2001, Hamano and colleagues [6] first described IgG4-RD noting an association between sclerosing pancreatitis and high serum levels of IgG4+. The recognition of other involved sites led to the concept of a fibro-inflammatory systemic disease. Large vessels involved by IgG4-RD [7] present clinically as aortitis or periaortitis. Notwithstanding, the corresponding lesions are similar throughout the different affected sites.⁸

CLASSIFICATION AND NOSOLOGY

Aortitis is classified into two main groups, according to the presence or absence of an infectious source. While infectious aortitis is now rare in developing countries as a result of the introduction of antibiotics, it nevertheless remains important to differentiate the infectious and non-infectious entities since the therapeutic strategies significantly differ [2].

Infectious aortitis develops in the course of septicemia or embolization of a septic embolus as a complication of infective endocarditis [1]. Pre-existing aortic wall damage in the form of arteriosclerotic lesions or vascular dilatation facilitates infection. Elderly men and immune compromised patients are populations at the greatest risk for the most common associated organisms, namely, gram-positive bacteria including *Staphylococcus* spp, *Enterococcus* spp and *Streptococcus pneumoniae* that typically involve the thoracic aorta; and gram-negative bacteria, notably *Salmonella* spp, that affect the abdominal aorta. Syphilitic aortitis develops in the setting of tertiary syphilis, typically involving the ascending aorta. *Treponema pallidum* preselects the *vasa vasorum* of the aortic wall leading to ischemic injury of the medial layer, with secondary aneurysmal dilatation. Tuberculous aortitis should be suspected in those with pulmonary and extrapulmonary tuberculosis in the course of miliary spread or direct extension of the infectious process from adjacent tissues, such as infected lymph nodes or lung lesions [2]. In those cases, the thoracic and abdominal aorta are affected with comparable frequency [1]. Fungal infection-related aortitis occurs in immune-compromised patients or in others chronically exposed to broad-spectrum antibiotics [1].

Table 1. Aortitis and periaortitis: Classification and etiologic basis

Infectious aortitis	Non-infectious aortitis	Idiopathic/IgG4 related periaortitis	Other diseases with periaortic infiltration
Bacterial (<i>Staphylococcus</i> spp, <i>Streptococcus pneumoniae</i> , <i>Salmonella</i> spp, <i>Escherichia</i> spp, <i>Treponema pallidum</i> , etc.)	Large-vessel vasculitides (Giant cell arteritis, Takayasu arteritis)	Idiopathic retroperitoneal fibrosis	Infections (Actinomycosis, Tuberculosis, Histoplasmosis)
<i>Mycobacterium tuberculosis</i>	ANCA associated vasculitides	Inflammatory abdominal aortic aneurysm	
Fungi (Candida, Aspergillus, Cryptococcus, Paracoccidioidomycosis)	Other vasculitides (Behçet Disease's, Cogan syndrome)	Perianeurysmal retroperitoneal fibrosis	Drugs (Ergot-alkaloid derived drugs, Methyldopa, Beta-adrenergic blockers, Phenacetin, Paracetamol, Aspirin, Hydralazine, Carboplatin, Methotrexate, Etanercept, Infliximab)
	Idiopathic/IgG4 related Isolated Aortitis	Thoracic periaortitis without aneurysm	
	Connective tissue diseases (Systemic lupus erythematosus, Relapsing polychondritis, Sarcoidosis)	Thoracic aorta aneurysm without periaortitis	Malignancies (Metastases of carcinomas: breast, lung, pancreas, stomach, colon, rectum, kidney, bladder, prostate, ovary and cervix; Carcinoid tumors, Hodgkin and non-Hodgkin lymphomas)
		Periaortitis with thoracic aorta aneurysm	
	Inflammatory arthritides (Rheumatoid arthritis, Ankylosing spondylitis)	Diffuse thoraco-abdominal periaortitis	Others (radiation therapy, abdominal trauma and surgery, Erdheim–Chester disease)

Non-infectious aortitis associated with LVV, including giant cell arteritis (GCA) and Takayasu arteritis (TA) represents two large groups of cases [2]. Aortic involvement occurs in systemic rheumatic disorders. Rheumatoid arthritis vasculitis (RAV), in which aortitis is an uncommon extra-articular manifestation, may be associated with vascular involvement of vessels of any size and may appear in any phase of the illness, although typically in the later stages [9]. The aortic root, the ascending aorta [10] and the branches of the aortic arch [11] can be involved in ankylosing spondylitis. Aortitis is also described in cases of systemic lupus erythematosus (SLE), most often manifesting as an aortic aneurysm or dissection [12, 13]; and in rare cases of relapsing polychondritis [14].

Large vessel involvement occurs in several small vessel vasculitides (SVV). In anti-neutrophil cytoplasm antibody (ANCA)-associated vasculitides (AAV), aortitis may present with stenosing arteritis, aneurysmal disease and aortic dissection [15]. Vasculitis involvement of the *vasa vasorum* affecting the aortic root is associated with valvular dysfunction in some cases of Behçet disease [16]. Aortitis also occurs in a minority of patients with Cogan syndrome [17] with severe incipient complications thereof [18]. Aortitis is unusual in sarcoidosis [19]. Cryptic isolated aortitis involving the ascending aorta may be detected in clinically asymptomatic patients, without evidence of a coexisting rheumatic disease [1].

Periaortitis has to be distinguished from aortitis not only for classification purposes, but also for its clinical and therapeutic implications. Periaortitis usually affects the infra-renal portion of the abdominal aorta and the iliac arteries. The aorta is undilated in idiopathic retroperitoneal fibrosis (RPF) while IAAA and perianeurysmal retroperitoneal fibrosis are the perianeurysmal forms [3]. Abdominal periaortitis must be differentiated from other diseases leading to periaortic retroperitoneal infiltration, particularly malignancies, granulomatous infections, drug-related and radiotherapy-induced conditions, and Erdheim-Chester disease [20]. In some patients, an idiopathic form of periaortitis involves the thoracic aorta with three possible patterns: thoracic periaortitis without aneurysm, thoracic aorta aneurysm without periaortitis, and periaortitis surrounding a thoracic aorta aneurysm.

Both aortitis and periaortitis can arise in the context of IgG4-RD signaling involvement as a multifocal disease; and in other cases, isolated to the thoracic tract. IgG4-related aortitis accounts for 75% of thoracic aortitis with a lymphoplasmacytic pattern [21]. Periaortitis is a common manifestation of IgG4-RD, responsible for up to 50% of periaortitis cases [22]. Table 1 summarizes the main etiologies of aortitis and periaortitis.

MAIN HISTOLOGIC PATTERNS

Aortitis may exhibit four different histological patterns of inflammation, namely granulomatosis/giant cell, lymphoplasmacytic, mixed inflammatory and suppurative, each related to different etiologies [1].

The *granulomatosis/giant cell pattern* is the most common pattern of inflammation in aortitis. It is characterized by the presence of large activated epithelioid macrophages with or without giant cells and compact granulomas. An accompanying lymphoplasmacytic infiltrate is often present. This pattern occurs in GCA- and TA-related aortitis, isolated aortitis, and aortitis associated with rheumatoid arthritis, ANCA associated vasculitides (AAVs), sarcoidosis, mycobacterial and fungal infections.

Figure 1. Histopathological findings in a case of IgG4-related aortitis. (A) (Hematoxylin and eosin, original magnification x4) shows inflammation and fibrosis involving the aortic adventitia and the periaortic soft tissue. Nodular lymphoplasmacytic infiltrates (long arrow) are seen in the context of abundant adventitial and periadventitial fibrosis. Fibrosis has an irregular pattern and is often organized around small adventitial and periadventitial vessels (short arrow). The arrowhead indicates the aortic media. (B) (Hematoxylin and eosin, original magnification x10) shows a detail of the image shown in (A) where a cluster of inflammatory mononuclear cells can be observed in the context of irregular fibrosis. Immunohistochemistry performed in this case (not shown) demonstrated an IgG4⁺/IgG⁺ plasma cell ratio of 50%.

The *lymphoplasmacytic pattern* consists of lymphocytes and plasma cells without a granulomatous/giant cell component. It is seen in IgG4-RD, SLE and syphilitic aortitis (Figure 1).

The *mixed inflammatory pattern* is relatively uncommon. The inflammatory infiltrate is composed of almost all inflammatory cell types: macrophages, lymphocytes, plasma cells, eosinophils, mast cells and neutrophils without a granulomatous component. It is associated with aortitis in Cogan's syndrome, Behçet disease and relapsing polychondritis.

The *suppurative pattern* is characterized by a marked neutrophilic infiltrate and extensive necrosis. This pattern occurs in some forms of infectious aortitis such as infections with Gram-positive cocci, *Salmonella*, *Pseudomonas* and fungi.

Idiopathic periaortitis (either IgG4-related or unrelated) histologically shows two components: a fibrous tissue and a chronic inflammatory infiltrate. The fibrous component includes an extracellular matrix of type I collagen fibers and a population of fibroblasts and myofibroblasts. The inflammatory infiltrate displays a *lymphoplasmacytic pattern*. It consists of B and T lymphocytes, macrophages, plasma cells and rare eosinophils [20].

The histopathological appearance of IgG4-related forms of aortitis and periaortitis is comparable to that of their IgG4-unrelated counterparts; however, the IgG4-related forms more frequently show a storiform pattern of fibrosis, lymphoid aggregates with germinal centers, tissue eosinophilia, and obliterative phlebitis, and by definition, a higher proportion of IgG4⁺ plasma cells. The diagnosis of IgG4-related forms requires a ratio of IgG4⁺/total IgG⁺ plasma cells > 40% [23].

CLINICAL PHENOTYPES

Herein, we describe the clinical phenotype of the most common aortitis and periaortitis syndromes, with particular emphasis on non-infectious forms, and we highlight the characteristics of these two conditions in the course of IgG4-RD.

Giant Cell Arteritis

This medium- and large-vessel vasculitis usually affects the aorta and its major branches with a predilection for the branches of the carotid and vertebral arteries [24]. Defined in the past as “temporal arteritis,” the term is inadequate to describe GCA because not all patients have temporal artery involvement and other categories of vasculitis can affect the temporal arteries. GCA is the most common type of non-infectious arteritis in North America and Western Europe. It occurs primarily in elderly individuals older than 50 years. Women are affected two to three times more commonly than men [25].

The typical histological pattern of GCA is a granulomatous inflammatory infiltrate composed of lymphocytes, macrophages and in 50% of the cases, multinucleated giant cells.²⁵ Inflammation has a focal nature, with “skip” lesions, wherein non-affected arterial segments intermingle with inflamed tracts. It is located mainly in the intima-media junction of the vessel wall but it can be present throughout the artery. At the beginning of the disease process, the intimal layer appears thickened by the inflammatory infiltrate and edema, at later stages by myofibroblast migration. The media remains well preserved, although focal smooth muscle necrosis may occur. The adventitia is inflamed in a moderate proportion of cases [26].

The pathogenesis of GCA has not been fully explained but dysregulated interactions between the vessel wall and the immune system are key to disease development [27]. The allelic variant of human leucocyte antigen (HLA)-DRB1*04 is the most common genetic association with GCA. The involvement of class II HLA molecules implies antigen-presentation to CD4⁺ T cells which then triggers the vasculitic lesion [28]. The involved antigens are still unknown, both infectious agents and autoantigens have been suspected.

Vascular dendritic cells located at the adventitia-media border of the artery have a critical role in the initiation of disease. Dendritic cells become activated once their toll-like receptors (TLRs) are engaged by microbial products and turn into non-tolerogenic cells able to present potential auto-antigens to T cells; their ability to produce chemokines is thus enhanced, thus leading to recruitment of T cells and macrophages into the vascular wall through the *vasa vasorum* [28]. The activated dendritic cells express CD86, a co-receptor required to trigger T-cell activation, and produce cytokines, such as interleukin (IL)-6 and IL-12 that guide the differentiation of T cells into selected functional lineages [27].

IL-6 is a pleiotropic cytokine released also by endothelial cells, vascular smooth muscle cells, lymphocytes and macrophages and implicated in the production of acute-phase proteins. IL-6 shifts T-cell differentiation towards the Th17 lineage and blocks the anti-inflammatory T regulatory cell expansion. Th17 cells produce a plethora of cytokines (IL-17, IL-21, and IL-22) that recruit macrophages and neutrophils and activate vascular smooth muscle cells, fibroblasts and endothelial cells.

The IL-6/IL-17 cytokine cluster seems to play an important role in early GCA, while the IL-12/IFN- γ cytokine cluster appears to drive the tissue remodeling during chronic disease [27]. IL-12 promotes the differentiation of the Th1 lineage, which releases IFN- γ into the microenvironment. IFN- γ amplifies T-cell responses and stimulates macrophage activation. Macrophages have the potential to induce arterial wall injury through multiple pathways. They release reactive oxygen intermediates and metalloproteinases that lead to the fragmentation of the internal elastic lamina. Macrophages produce also platelet-derived growth factor (PDGF) and vascular endothelial growth factor that are critically involved in intimal layer proliferation. Myofibroblasts, stimulated by IFN- γ and PDGF migrate in the intima where they replicate and secrete extracellular matrix leading to concentric intima hyperplasia [28]. Outgrowth of the intima is consistently associated with marked neoangiogenesis. The end result is a vascular occlusion caused by the vessel wall thickening or the formation of arterial aneurysm (particularly thoracic aorta aneurysm) caused by destruction of the arterial wall [28].

Medium-sized arteries, such as the branches of external and internal carotid arteries and the vertebral arteries respond with occlusion of the lumen and, consequently, ischemic organ damage. Clinical symptoms reflect end organ ischemia.

The classic manifestations are headache, scalp tenderness, jaw claudication, blindness, stroke, transient ischemic attacks and vertigo. Similarly, involvement of the subclavian, axillary, and proximal brachial arteries leads to arm claudication and absent or asymmetric pulses [28]. Compared to patients with cranial symptoms, those with aortic arch syndrome tend to be younger at diagnosis and have a longer duration of symptoms prior to diagnosis [29].

Instead of forming stenotic lesions, the aorta responds with wall destruction. Aortitis most often occurs in the thoracic aorta while involvement of the branches of the abdominal aorta and lower extremity arteries is less common. It may produce chest or back pain but it is more frequently asymptomatic until complications arise. These complications are aneurysm formation and rupture, dissection and aortic valve insufficiency (Figure 2). In early studies, the prevalence of aortic involvement in patients with GCA was based on the rate of aneurysm diagnosed fortuitously or after acute events and autopsy data, remaining under-estimated. Recently, the large use of imaging techniques (essentially CT, MRI or PET) in the diagnosis and follow-up of LVVs showed that aortic involvement may be more prevalent than previously reported, with a frequency ranging from 33%³⁰ to 50% [31-33]. The risk of aortic structural damage significantly increases in the first 5 years from diagnosis and progresses slowly afterwards, suggesting that chronic inflammation of the vascular wall is the major determinant of aortic damage [34].

In almost all patients with GCA, a syndrome of systemic inflammation accompanies vascular manifestations and presents with nonspecific symptoms including malaise, anorexia, weight loss, fever and depression. Around 40% of patients with GCA also have polymyalgia rheumatica, characterized by aching and morning stiffness involving the neck, shoulder and pelvic girdles [25].

Takayasu Arteritis

This disease predominantly affects the aorta and its major branches, along with pulmonary arteries. In accordance with the Chapel Hill consensus conference nomenclature, TA is a granulomatous vasculitis that usually occurs before the age of 50 years [24]. It is a rare disease with few reports regarding prevalence and incidence. Nonetheless, the highest prevalence has been described in Japan with 40 cases/million [35], but incidence rates seem to be similar in different countries worldwide [36]. It affects predominantly young women, with a peak incidence around the second and third decade [36].

The inflammatory process is a panarteritis affecting all the three layers of the vessels, with a focal distribution, which results in narrowing of the lumen due to the fibrosis with stenosis and occlusion, or aneurysmal formation in cases where the process is more rapid [26, 37].

In the acute phase, *vasa vasorum* of the adventitia appear inflamed with granulomatous inflammatory infiltrates involving the media, too. The most abundant cells are T and B cells, along with granulocytes and eosinophils. Giant cells are present as in GCA and this feature may account for the difficulties in differentiating the two vasculitides. Neovascularization and proliferation of the smooth cells and fibroblasts lead to derangement of the intima. In chronic stages of the disease fibrosis and dense scarring lead to a thickening of the adventitia and the intima appears as a “tree bark,” a characteristic common to other aortitides. The disruption of the elastic fibers may lead to aneurysm formation (Figure 2) [1, 37].

The pathogenesis of TA is not well understood. Various antigens have been explored but the exact triggers and involved immunologic pathways remain obscure. Current evidences suggest an autoimmune mechanism with a prominent cell-mediated immunity, along with genetic predisposition mediated by HLA alleles. In particular a strong association was reported between class I HLA alleles and TA [38].

Figure 2. Computed tomographic (CT) findings in aortitis. The images A-C show the CT appearance of thoracic aortitis: (A) aneurysms of ascending (upper arrow) and descending aorta (lower arrow); (B, C): wall thickening of the aortic arch (B, arrow) and of the descending aorta (C, arrow). CT appearance of abdominal aortitis (D, arrow).

Natural killer (NK) cells and $\gamma\delta$ T lymphocytes appear to have a role in inducing apoptosis of the vascular cells by releasing perforin. These cells are activated by 65-kDa heat shock protein (HSP) which is overexpressed in aortic samples of patients affected by TA [39]. Similar to GCA, CD4⁺ T cells have a leading role particularly in the formation of granulomas. Both Th1 and Th17 pathways are expanded and correlate with disease activity [40].

The clinical manifestations are variable during the early stages of the disease with anorexia, fever and malaise. In fibrotic stages (also known as pulseless stages) symptoms are related to vascular stenosis and aneurysms [41]. Most typical clinical features include: diminished or absent pulses with limb claudication and discrepancies in blood pressure, multiple vascular bruits, renovascular hypertension and retinopathy [37]. Complications are related to organ ischemia and congestive heart failure due to hypertension and valve regurgitation when thoracic aneurysms are present.

Isolated Aortitis

Isolated aortitis is a single-organ vasculitis found primarily in the ascending part of the thoracic aorta [24]. This condition is not a component of a systemic vasculitis like GCA and TA, or associated with a systemic disease such as SLE or sarcoidosis. The disorder emerged with the advent of aortic surgery and histopathologic examination of the aortic surgical specimens. The introduction of new imaging techniques facilitated recognition of the disease before development of structural aortic abnormalities requiring surgery.

The epidemiology of isolated aortitis has not been clearly established, but its prevalence is probably underestimated, as the disease may remain undiagnosed for a long time. The incidence of isolated aortitis in the population of patients undergoing thoracic aortic surgery is between 3.8% and 4.4% [42-44]. Some studies show a higher incidence in women [42, 43] others in men [44, 45]. The mean age of patients at diagnosis ranges from 63 to 72 years [42-44]. Unlike those with TA and GCA, patients with isolated aortitis do not have symptoms related to systemic illness or extra-aortic arteritis [43].

Most cases of isolated aortitis show a granulomatous/giant cell pattern of inflammation localized in the medial layer. The inflammatory infiltrate comprises macrophages, giant cells, lymphocytes, plasma cells and well-formed granulomas replacing irregular areas of medial destruction. Adventitial inflammation contains minimal mononuclear cell infiltration without granuloma formation.

Isolated aortitis is identified incidentally during radiological exams or in the repair of the complications of aortic surgery [46]. Isolated aortitis can lead to thoracic aortic aneurysms, aortic dissection and aortic valve regurgitation. The aortic aneurysm is certainly the most frequent complication, so noted in 95% of patients with isolated aortitis and is usually localized in the ascending tract [42, 43].

Recent studies have evaluated the rate of new aortic events in patients with the diagnosis of isolated aortitis [47, 48]. Follow-up data indicate that patients with isolated aortitis are at increased risk for subsequent aortic events, such as new aneurysms and dissections also involving the descending thoracic aorta or the abdominal aorta. Even in the absence of signs of systemic vasculitis, aortitis identified in the ascending aorta is associated with an increased frequency of distal aortic events during long-term follow-up. Patients with isolated aortitis should be monitored with periodic aortic imaging.

Though the studies are limited, there is an increasing evidence that patients with aortitis isolated to aortic ascending segment have actually a smoldering systemic vasculitis that is subclinical in other districts at the time of presentation and fully manifests at a later time [46].

IgG4-Related Aortitis

Since the first description of IgG4-RD, diverse clinical entities without clear nosology have been categorized in the spectrum of this systemic fibro-inflammatory disease, including cases of aortitis, once considered isolated or idiopathic.

IgG4-related aortitis preferentially affects the thoracic aorta and particularly the aortic arch [21, 49]. It presents with a lymphoplasmacytic pattern and accounts for a significant proportion of non-infectious thoracic aortitis cases, and about 75% of cases of lymphoplasmacytic thoracic aortitis [21, 50]. The vasculitic process can also involve the abdominal aorta, along with medium-sized vessels originating from the aorta, such as the carotid and coronary arteries [7, 51]. Small vessel involvement has also been described, thus supporting the idea that IgG4-RD may be included in the category of vasculitis of vessels of variable size [52].

IgG4-related aortitis occurs among elderly men aged 60 years or older, in keeping with the epidemiology of the systemic and other organ-limited forms of IgG4-RD [50].

The inflammatory infiltrate affects predominantly the adventitia with a lesser involvement of the media (Figure 1), in contrast with other LVV.¹ Histological findings are typical and are the same throughout different lesions, regardless of the involved site. The main features are storiform fibrosis, obliterative phlebitis, moderate eosinophilia and dense lymphoplasmacytic infiltrates, with a predominance of T and B cells that occasionally organize into germinal centers [23]. IgG4-immune staining of the affected tissue is mandatory to have a “definite” diagnosis of IgG4-related aortitis. However, in cases not undergoing surgery or when the pathological specimen is unavailable, evidence of aortitis on imaging studies, along with increased serum IgG4 levels, supports a “possible” diagnosis of this condition [49].

The pathogenesis of IgG4-RD, and consequently of IgG4-related aortitis, remains unclear although significant advances have been made: IgG4 antibodies does not seem to have a central role, and their anti-inflammatory characteristics lead to consider them as an attempt to dampen a primary inflammatory process [53]. The immune mechanisms are probably cell-mediated. A subpopulation of CD4⁺ T cells with a cytotoxic phenotype (CTLs) has been found in IgG4-RD lesions and clonally expanded in the circulation, which appears to orchestrate the pathogenic mechanisms activated by antigen-presenting B cells [54]. The latter have a pivotal role in initiating and maintaining the disease, as shown by the efficacy of B cell-depleting therapies, such as rituximab. The antigens that trigger the immune response are unknown.

IgG4-related aortitis occurs sub-acutely and is often asymptomatic. It may be diagnosed after an incidental finding on CT (Figure 2) or after pathological examination of surgical specimens. It can also present with symptoms related to the presence of aneurysms, whereas end organ ischemia is far less common and appear when medium-size vessels such as the main aortic branches are also involved [7]. Acute pain may indicate dissection, which has also

been described as a complication of IgG4-related aortitis [55]. Involvement of other organs may be absent at onset and appear only during follow-up with a metachronous pattern [56], leading to difficulties in promptly recognizing IgG4-RD. The most frequent clinical pictures of IgG4-RD include sclerosing pancreatitis (type 1 autoimmune pancreatitis), Mikulicz disease and RPF, but several other conditions may be found such as diffuse lymphadenopathy, sclerosing cholangitis, pseudotumor of the orbit, and tubulo-interstitial nephritis.

Periaortitis

Periaortitis is a fibroinflammatory disorder characterized by the presence of fibrosis accompanied by a variable number of chronic inflammatory cells that extend from the adventitia of the aortic wall into the surrounding periaortic space [57]. The term “chronic periaortitis,” proposed by Mitchison in 1980 underlines the nature of the inflammatory infiltrate and has traditionally been applied to describe this condition.

Periaortitis includes three main entities: idiopathic RPF, inflammatory abdominal aortic aneurysms (IAAAs) and perianeurysmal RPF. In idiopathic RPF, the aorta is undilated and the retroperitoneal fibroinflammatory tissue frequently entraps neighboring structures such as the ureters and the inferior vena cava (Figure 3); in IAAAs, the mass develops around a dilated aorta without involving adjacent organs (Figure 3). Perianeurysmal RPF represents a combination of these two diseases, the aorta is dilated and the periaortic tissue causes obstruction of other structures.

Figure 3. CT findings in periaortitis. The images show the CT appearance of periaortitis with typical localization (A), where the soft-tissue mass (arrow) surrounds the anterior and lateral sides of the abdominal aorta, spreads to the right ureter and causes hydronephrosis. CT appearance of perianeurysmal periaortitis (B): the fibro-inflammatory tissue encircles a dilated abdominal aorta (arrow). CT appearance of thoracic periaortitis (C, D). The perivascular tissue surrounds the ascending thoracic aorta (C, upper arrow), the aortic arch (D, arrow) and the descending thoracic aorta (C, lower arrow).

Periaortitis is a rare disease and data about its epidemiology are limited to idiopathic RPF and IAAAs. The incidence of idiopathic RPF is 0.1-1.3 per 100,000 person-years and its prevalence 1.4/100,000 inhabitants [58, 59]. IAAAs represent 4-10% of all abdominal aortic aneurysms [60]. The mean age at onset is 50-60 years [61], although rarely cases have been reported in pediatric patients [62]. Men are affected two to three times more often than women and this ratio is higher in the aneurysmal forms [58].

Pathologic changes in periaortitis involve both the aortic wall and the surrounding soft tissues. The typical macroscopic appearance of periaortitis is that of a greyish mass infiltrating the retroperitoneal tissue surrounding the abdominal aorta, the iliac arteries and, in most cases, the inferior vena cava and the ureters [63]. The mass usually develops between the origin of the renal arteries and the pelvic brim. In some instances, periaortitis shows atypical localizations, which might be peri-duodenal, peri-pancreatic, pelvic, presacral, peri-ureteral or peri-renal and not characterized by involvement of the periaortic space. These cases are thought to have a different pathogenesis.

Microscopic examination reveals the presence of two components: a fibrous tissue and an inflammatory infiltrate [20]. The fibrous component comprises fibroblasts that show signs of activation and transition into myofibroblasts (α -smooth muscle actin expression) and produce an extracellular matrix composed of type I collagen fibers organized in thick irregular bundles. The inflammatory infiltrate consists of numerous lymphocytes, plasma cells, macrophages and scattered eosinophils. The inflammatory cells are interspersed within the collagen bundles (diffuse pattern), but also organized in nodular aggregates, usually around small vessels (perivascular nodular pattern). These aggregates have a B-cell core surrounded by T cells, which are predominantly CD4⁺. In some cases, these lymphoid follicles have the structure of germinal centers, which is a sign of ectopic lymphoneogenesis, thus proving the presence of a highly structured immune-mediated/autoimmune response.

The aortic wall shows intimal atherosclerosis, medial thinning and adventitial inflammation and fibrosis. The composition of the inflammatory infiltrate in the aortic adventitia is similar to that of the retroperitoneal one. When the pattern is arranged in nodular aggregates, these are usually centered on the adventitial *vasa vasorum* which can show signs of vasculitis [64].

The pathogenesis of periaortitis is still unclear. The theory proposed by Parums and Mitchinson suggests that it is due to a local inflammatory reaction against antigens localized in the atherosclerotic plaques of the aorta such as oxidized low-density lipoproteins or ceroid [65, 66]. These antigens would be presented by plaque macrophages to B and T lymphocytes residing in the adventitia, where they would elicit a fibro-inflammatory response inducing lymphocyte activation and immunoglobulin production. This theory, however, cannot explain the presence of constitutional symptoms and the increase in acute phase reactant levels in patients with periaortitis, and the frequent associations with autoimmune or fibro-inflammatory diseases involving other organs. Additionally, periaortitis may affect patients without atherosclerotic lesions and involve vascular territories/segments spared by atherosclerosis [67]. Recently, it has been proposed that periaortitis may actually be a systemic autoimmune disease rather than the result of a local inflammatory reaction [64]. This theory is supported by similarities to systemic LLV, such as GCA and TA: the inflammatory process starts in the adventitial layer leading to perivascular infiltrates surrounding aortic *vasa vasorum*. Thus, it cannot be excluded that periaortitis originates as a primary aortitis which subsequently induces a fibro-inflammatory reaction into the periaortic space [3].

The pathogenesis of the disease is probably multifactorial, recognizing genetic, environmental and immune-mediated determinants. The role of genetic factors is demonstrated by the association between periaortitis and the HLA class II allele HLA-DRB1*03, a marker of autoimmune diseases such as SLE, type 1 diabetes, autoimmune thyroiditis and myasthenia gravis [68].

A more recent study also describes an increased susceptibility to the aneurysmal forms of periaortitis in patients carrying the $\Delta 32$ polymorphism of the *CCR5* gene [69]. *CCR5* is expressed on many immune cells, particularly Th1 cells, and acts by binding to different chemokines, including RANTES, MIP-1a and MIP-1b. The *CCR5* $\Delta 32$ polymorphism creates a truncated, nonfunctional receptor and probably shifts the immune response toward a Th2 pattern.

Among environmental agents, cigarette smoking and asbestos exposure are significantly associated with an increased risk of developing the disease. Interestingly, smoking and asbestos had a multiplicative effect on disease risk, with an odds ratio of 12.04 (95% confidence interval, 4.32 to 38.28) in co-exposed subjects [70]. The role of other environmental or infectious agents remains elusive.

The immunopathogenic model of periaortitis is based on the hypothesis that the disease is antigen-driven, although the triggering antigens are still unknown. Based on the available experimental evidence, it can be postulated that antigen-presenting cells present such hypothetical antigens to CD4⁺ T cells within the aortic wall, probably in the adventitia. CD4⁺ T cells expand, secrete IL-6 [71], which enhances the production of acute-phase proteins and promotes the activation of B cells and fibroblasts. CD4⁺ T cells also secrete Th2 cytokines such as IL-4, IL-10 and IL-13, which induce B-cell expansion and maturation into plasma cells producing, in a fraction of cases, IgG4. Lymphoid cells also release eotaxin-1 (also known as CCL11), which drives tissue infiltration by eosinophils and mast cells, whose products induce fibroblast activation [72]. Once activated, fibroblasts mature into myofibroblasts and secrete collagen, promoting fibrosis. The pathogenic importance of IL-6 and of B cells was confirmed *in vivo* by the efficacy of therapies targeting selectively the IL-6 receptor (tocilizumab) and the B-cell marker CD20 (rituximab) [71, 73].

The clinical presentation of periaortitis includes two types of manifestations: localized, due to the compressive effects of the retroperitoneal mass, and systemic, related to the inflammatory nature of the disease. The more frequent localized symptom, present in about 80% of the patients, is side, back or abdominal pain. It is usually described as persistent and dull, not exacerbated by movement or palpation; it transiently responds to nonsteroidal anti-inflammatory drugs and, in cases of ureteral involvement, it can be colic-like [3]. Ureteral involvement is the most frequent complication and can be unilateral or bilateral. In cases with unilateral involvement, ureteral obstruction can also be asymptomatic for a long time and, at diagnosis, these patients present with renal hypoplasia/atrophy, whose frequency is estimated to be up to 30%. However, most cases are symptomatic and bilateral involvement usually leads to acute renal failure. Other urologic manifestations are frequent: they range from testicular pain, often accompanied by hydrocele and/or varicocele due to spermatic vein encasement by periaortitis, to retrograde ejaculation and erectile dysfunction [20]. The extrinsic compression of retroperitoneal lymphatic vessels and veins can be the cause of lower extremity edema and deep vein thrombosis. Claudication and intestinal ischemia are

less common. Systemic symptoms include fatigue, weight loss, anorexia, sleep disturbances and low-grade fever [3].

Periaortitis can affect not only the lower abdominal aorta and the iliac arteries but also other vascular segments. This may suggest that in such cases, periaortitis actually represents a primary, diffuse inflammatory disease of the aorta and its major branches (Figure 3) [5]. In 1970, Mitchinson described for the first time the presence of mild inflammation and fibrosis in the adventitial layer of the thoracic aorta in autopsy studies performed on patients with abdominal periaortitis [4]. Subsequent reports have also documented the involvement of coronary arteries [57], renal arteries [74], and celiac axis, superior and inferior mesenteric arteries [75].

A recent study performed in a large cohort of patients showed that, in one third of cases, periaortitis might also affect the thoracic aorta and the epiaortic arteries [5]. The perivascular tissue may develop around the ascending aorta, the aortic arch, the descending aorta and the origin of epiaortic arteries. Three main patterns can be observed: periaortitis with thoracic aorta aneurysm, thoracic periaortitis without aneurysm and thoracic aorta aneurysm without periaortitis [5]. Histology of the thoracic tissue is definitely similar to that found in abdominal periaortitis. The pathological lesions involve the adventitia and the periadventitial tissue and consist of a fibrous component and a chronic inflammatory infiltrate comprising lymphocytes, histiocytes, plasma cells, and eosinophils.

The observation that the thoracic aorta is usually spared by atherosclerosis strongly supports the hypothesis that, when periaortitis develops, it is a primary immune-mediated process [76]. The clinical presentation of thoracic involvement in periaortitis includes specific symptoms such as laryngeal nerve paralysis, dry cough, upper limb claudication and paresthesias; however, in about 85% of cases it is asymptomatic. Interestingly, the comparison of demographic and clinical characteristics of patients with and without thoracic involvement revealed that these subgroups were different. Patients with thoracic involvement had a significantly higher female prevalence, a greater age at disease onset, a higher prevalence of systemic symptoms and of back or abdominal pain [5].

The female prevalence and the advanced age in patients with thoracic aorta involvement is a feature shared by GCA, which often affects not only the epiaortic tree but also the thoracic aorta. Indeed, GCA is characterized by only mild periaortic thickening does not cause obstructive uropathy, while periaortitis, on the other hand, does not lead to typical GCA-related cranial symptoms. However, the differential diagnosis between GCA and periaortitis may become more challenging when patients present with non-specific systemic symptoms, including fever of unknown origin, and lack clinical manifestations specific for either disease.

Periaortitis may be associated with a large variety of autoimmune conditions. This observation underlines the relevance of autoimmune mechanisms in the pathogenesis of the disease. Hashimoto's thyroiditis is the most commonly associated autoimmune disorder; it may arise together with periaortitis, but it can also precede or follow periaortitis diagnosis. Overall, it has been reported that 25% of patients with periaortitis develop hypothyroidism after a median follow-up of 45 months [77]. Other associated conditions are AAV, particularly granulomatosis with polyangiitis, membranous nephropathy, SLE, rheumatoid arthritis, uveitis and psoriasis [3].

IgG4-Related Periaortitis

Periaortitis may also be a manifestation of IgG4-RD. Histological examination is mandatory to differentiate IgG4-related and -unrelated forms. However, the coexistence of other clinical conditions belonging to the spectrum of IgG4-RD may help classify periaortitis as IgG4-related [78].

Periaortitis (particularly the abdominal form) is reported among the most frequent manifestations of IgG4-RD in different studies, even if its prevalence remains quite variable, ranging from 11% to 30% [79-82]. It appears that environmental factors influence the different organ involvements, since periaortitis is more frequent in Western cohorts, whereas in Asian countries extra-vascular lesions are more common [82].

IgG4-related periaortitis may differ from IgG4-unrelated forms in terms of microscopic findings, whereas the macroscopic ones are very similar. In particular, there were no significant differences in disease localization and characteristics when CT or MRI findings were compared [83, 84]. IgG4-related IAAAs (which are considered perianeurysmal forms of periaortitis) are frequently saccular, as the IgG4-unrelated ones, but the former show a more prominent thickening of the wall due to the fibrotic tissue which is also adherent to neighboring structures, leading to an apparently lower risk of rupture [85]. IgG4-related periaortitis is distinguishable from its IgG4-unrelated counterpart especially for the organization of the fibrotic tissue, which is storiform in the former, resembling the spokes of a cartwheel. IgG4-unrelated forms usually do not show obliterative phlebitis, and the inflammatory infiltrate is less dense and not markedly enriched with IgG4⁺ plasma cells and eosinophils [83]. However, these differences may be only slight, and it must be emphasized that the background histologic appearance of IgG4-related and -unrelated forms is often very similar, thus leading to the concept that these two entities may represent different ends of the same spectrum.

From a clinical standpoint, there are no substantial differences, except for a male predominance in IgG4-related forms [86]. The clinical manifestations of both IgG4-related and -unrelated periaortitis are comparable, with flank and abdominal pain being the most common presenting symptom. However, it must always be remembered that IgG4-related forms are more commonly associated with extra-retroperitoneal manifestations of IgG4-RD; this may help clarify the clinical picture of the disease.

DIAGNOSIS

The differential diagnosis among different forms of inflammatory aortitis and periaortitis is challenging, and histological examination is often required to have a clear definition of the disease. The particular site of inflammation makes it difficult to perform biopsies, unless aortic or retroperitoneal/ureteral surgery is required. Therefore, in most cases the diagnosis is based on laboratory tests and imaging studies, along with clinical presentation.

Aortitis in Large-Vessel Vasculitides

Both GCA and TA often manifest with typical symptoms, which render them more easily recognizable than other cases of apparently idiopathic aortitis. Cranial symptoms (e.g., jaw claudication, scalp tenderness and visual alterations) usually occur in GCA, whereas TA may manifest with signs and symptoms related to vascular stenosis (e.g., absence of pulses, bruits, limb claudication) [87]. Acute-phase reactants, namely C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are high in most cases of GCA whereas they are frequently normal in TA, which is in line with the clinical presentation of TA, whose clinical manifestations often arise in a late, “fibrotic” stage.

Figure 4. ^{18}F -fluorodeoxyglucose (FDG) positron emission tomography (PET) findings in patients with periaortitis and/or aortitis. (A) ^{18}F -FDG PET findings in a patient with abdominal periaortitis and thoracic aortitis. The scans show intense FDG uptake at the level of the thoracic aorta (long arrow) and of the abdominal aorta (short arrow). (B) ^{18}F -FDG PET findings in a patient with giant cell arteritis. The scans show intense FDG uptake at the level of the aortic arch (long arrow) and of the axillary arteries (short arrow).

Imaging studies, such as ultrasonography (US), angio-CT and angio-MRI have become crucial for the diagnosis of GCA and TA: mural thickening and enhancement are typical findings [88]. CT and MRI also show some disease-related aspects that are essential for the differential diagnosis between aortitis and periaortitis, since aortitis (also that occurring in

GCA or TA) does not have the thick periaortic cuff that characterizes CP and does not lead to encasement of neighboring structures such as ureters and inferior vena cava [76]. Over the last few years, ^{18}F -FDG PET (Figure 4) has become part of the diagnostic armamentarium of LVVs, and has allowed detection of aortic involvement. The advantage of PET is that it is a whole-body imaging study, able to reveal other FDG-avid lesions, and that it provides a measurable degree of FDG uptake by means of the maximal standardized uptake value (SUVmax) that can be useful to monitor vascular inflammation. Despite its widespread use in patients with LVV, ^{18}F -FDG PET still has an uncertain role as predictor of response or as disease-monitoring tool [88].

In patients with GCA, temporal artery biopsy remains the principal diagnostic examination; however, it must be recognized that a fraction of GCA patients may lack temporal artery involvement, and this is particularly the case of those with diffuse involvement of large arteries including the aorta. In sum, the diagnosis of GCA and TA, and consequently of aortic involvement in these conditions, relies on the integration of clinical examination, laboratory tests, imaging studies and, particularly in the case of GCA, vascular (temporal artery) biopsy.

Isolated Aortitis

Isolated aortitis is by definition a vasculitis confined to the aorta, in the absence of symptoms related to other systemic diseases [24]. It tends to affect mostly the thoracic aorta in its ascending part and usually presents as a thoracic aortic aneurysm [42]. It is often an incidental finding that can be diagnosed in two distinct settings. Traditionally and most commonly, the disorder is diagnosed pathologically following surgical resection of an aortic segment for aneurysm or dissection, and the patient is clinically found to have no other signs or symptoms of vasculitis. Isolated aortitis can also be identified radiologically, most often by CT or MRI, as an isolated aneurysm or as wall thickening limited to one segment of the aorta [46]. The absence of a diffuse atherosclerotic disease or of common risk factors for atherosclerosis should heighten suspicion of isolated aortitis in patients showing the above abnormalities on CT or MRI.

Once imaging studies disclose an apparently isolated aortitis, and the patient has no associated rheumatologic diseases, it is mandatory to exclude infectious causes (Table 1); laboratory tests can be useful in this setting to rule out particularly syphilis and tuberculosis and, in patients with systemic infections or in immunocompromised subjects, fungal and bacterial etiologies. Finally, the diagnostic work-up of an isolated aortitis should also consider the exclusion of IgG4-RD, of which aortitis can also be the sole manifestation. Therefore, in the absence of a biopsy, testing serum IgG4 levels and searching for other sites potentially involved by the disease is recommended (see below).

Periaortitis

The diagnosis of periaortitis is usually based on imaging studies and requires histological confirmation only in a small proportion of patients. Indeed, the clinical signs and symptoms

at disease presentation, as well as the laboratory tests are quite non-specific. Ultrasound is usually performed at onset and may detect both aneurysmal aortic dilatation and periaortitis as a hypoechoic periaortic halo. It also allows the detection of hydronephrosis; such US findings are crucial both at diagnosis and during the follow-up.

On CT, periaortitis appears as a homogeneous, plaque-like tissue, isodense to muscle, which develops around the anterolateral sides of the abdominal aorta. In the retroperitoneum, it may encase the ureters, drawing them medially, and also cause inferior vena cava compression [67]. On MRI, the inflammatory aortic/periaortic thickening and the tissue surrounding the vessels are seen as hypointense on T1-weighted images, while they are hyperintense on T2-weighted images during active disease phases, due to the presence of edema and hypercellularity. Contrast-enhancement, both on CT and MRI, is more pronounced during the early disease stages [89].

^{18}F -FDG PET is increasingly used for the diagnosis of periaortitis, although its specificity is low given that forms of periaortitis secondary to infections or neoplasms may also be FDG-avid. However, ^{18}F -FDG PET has the advantage of being able to provide whole-body imaging of metabolically active lesions, thus allowing both the detection of other vascular segments (Figure 4) involved by periaortitis and of occult neoplastic or infectious foci. In patients with multifocal fibroinflammatory conditions (e.g., periaortitis and mediastinal fibrosis), ^{18}F -FDG PET can be positive at different sites [90]. Interestingly, ^{18}F -FDG PET recently proved able to predict response to therapy, since metabolically inactive periaortitis is less likely to respond to glucocorticoid treatment than totally inactive lesions. However, no significant differences in response to treatment were detected among patients with different degrees of FDG uptake [91].

Periaortic retroperitoneal biopsy is recommended in all cases of difficult interpretation, especially when there is suspicion of infections or malignancies, and in patients not responsive to treatment. Patients with atypical presentations usually undergo diagnostic biopsies.

Aortitis and Periaortitis in IgG4-Related Disease

As reported above, aortitis and periaortitis may arise in the context of IgG4-RD. In 2008, criteria were proposed for the diagnosis of IgG4-RD [92]. They include: i) typical organ involvement (pseudotumoral lesions) with organ swelling and/or dysfunction; ii) histologically compatible features and immunohistochemical evidence of IgG4⁺/IgG⁺ plasma cells >40% together with IgG4⁺ plasma cells >10/hpf; iii) serum IgG4 level >135 mg/dl. The diagnosis is considered to be “definite” when all three criteria are fulfilled, “probable” when i) and ii) are met, and “possible” when i) and iii) are met and histopathology is either unavailable or non-diagnostic. These criteria are widely used, even if their specificity and sensitivity still warrant validation.

It has been reported that in aortic and periaortic tissue, immune staining findings might be inconsistent with a diagnosis of IgG4-RD, even on a background where the three main characteristics (storiform fibrosis, obliterative phlebitis and lymphoplasmacytic infiltrate) are represented [93]. In these cases the diagnosis of IgG4-RD relied upon morphological findings, along with clinical and imaging data.

Laboratory abnormalities that can be found in IgG4-RD include elevation of acute-phase reactants, especially in cases with multifocal involvement, and polyclonal hypergammaglobulinemia. Peripheral eosinophilia and serum IgE increase may be encountered in about a third of cases. Positive ANCA with specificity for either myeloperoxidase or proteinase 3 may also occur, indeed overlap forms of IgG4-RD and AAV have recently been described [94].

The same imaging studies used for the diagnosis and follow-up of aortitis and periaortitis not associated with other IgG4-related lesions are employed for cases arising in the context of IgG4-RD. Thus, US, CT or MRI and ^{18}F -FDG PET may all be helpful both at diagnosis and during the follow-up to detect the major involved sites and to assess their metabolic activity, although the FDG-avidity of the different IgG4-related lesions varies widely. Typical findings are tumor-like lesions, which may be diffuse, leading to an enlargement of the involved organ, or focal. These aspects make IgG4-RD a mimicker of malignancies: in these cases biopsy is the only way to differentiate them.

Other Diseases with Periaortic Involvement

Periaortic infiltration may be observed in other disorders (Table 1) that should be excluded before arriving at the diagnosis of periaortitis, whether IgG4-related or not. Unfortunately, an increase in serum IgG4 has little value in the differential diagnosis between IgG4-related cases and secondary forms.

Malignancies may resemble periaortitis [95] and in these cases imaging studies play a fundamental role. Indeed, on CT and MRI neoplastic forms appear to be inhomogeneous and lobulated, more adherent to surrounding organs with no clear cleavage site, and often extend above the origin of the renal arteries, unlike typical periaortitis [96, 97]. In addition, periaortitis is usually located anterolateral to the aorta, whereas neoplastic masses are also anterior to the spine and tend to displace the aorta anteriorly.^{96,97} Moreover, malignancies may also infiltrate muscles and erode bones [98].

One large retrospective study evaluated the utility of ^{18}F -FDG PET in differentiating neoplastic forms from idiopathic/IgG4-related ones [99]. It was reported that malignancies could have a greater FDG avidity; moreover, PET allows detection of all neoplastic sites, if the neoplasm itself is FDG-avid.

A rare cause of aortic wall and periaortic involvement is ECD, a non-Langerhans cell histiocytosis with predilection for long bones, cardiovascular system, central nervous system, and endocrine glands [100]. Interestingly, ECD can involve both the thoracic and abdominal aorta, giving rise to an aspect usually reported as “coated aorta.” On imaging ECD should be suspected when the fibrous tissue surrounds the kidneys, showing the typical finding of “hairy kidneys” [101]. In these cases, a biopsy is recommended, indeed morphological and immune staining features are very different in ECD versus idiopathic periaortitis. Typical findings in ECD include tissue infiltration by CD68⁺ CD1a⁻ “foamy” histiocytes, along with diffuse lymphoplasmacytic infiltrates and abundant fibrosis [102].

The conditions (Table 1) that can result in secondary forms of periaortic disease include drugs, surgical procedures, radiotherapy and trauma [98, 103], that may be excluded by a careful review of the patient’s medical history.

PRINCIPLES OF TREATMENT

A detailed review of the treatment of all causes of aortitis and periaortitis is beyond the scope of the present chapter. However, it is important to outline some aspects. The exclusion of neoplastic, infectious and other proliferative (e.g., ECD) causes of aortic disease have obvious therapeutic implications since most of the idiopathic forms of aortitis and periaortitis are treated with glucocorticoid and immunosuppressive therapies. It is also important to carefully differentiate aortitis/periaortitis occurring in the setting either of LVV, systemic connective tissue or small-vessel vasculitic syndromes, or fibro-inflammatory disorders including IgG4-RD. LVVs are treated with glucocorticoids and or other conventional immunosuppressants, and only recently biologic therapies (particularly the anti-IL6 receptor antibody tocilizumab) have been introduced for the management of GCA [104]. The treatment of aortitis associated with systemic connective tissue diseases as well as systemic small-vessel vasculitis varies depending on the underlying condition; generally, the occurrence of aortitis is considered a severe complication, requiring aggressive immunosuppression. Idiopathic aortitis and periaortitis, whether isolated or in the context of IgG4-RD, are generally corticosteroid-sensitive, and therefore corticosteroids should be considered first-line treatment. In relapsing or difficult-to-treat cases, rituximab has recently proved effective [73, 105]. Aortitis and periaortitis may lead to aneurysmal dilatation of both the abdominal and thoracic aorta that requires evaluation by vascular surgeons as prompt treatment using endovascular or surgical techniques may prevent life-threatening complications.

CONCLUSION

Inflammatory aortitis and periaortitis are inflammatory diseases of varying etiology, and recognition of them is critical for optimal management. Imaging studies such as CT, MRI, and ¹⁸F-FDG-PET are widely used for their management and follow-up. Diagnostic biopsies are required in a fraction of cases, with histological patterns that may range from lymphoplasmacytic to granulomatous and suppurative presentations. The treatment will differ depending on the cause, with isolated cases and those suffering from systemic immune-mediated conditions, managed with a combinations of corticosteroids and immunosuppressive drugs. Surgical evaluation may be required in cases presenting with significant aneurysmal dilatation, or with less common complications such as dissection and rupture.

ABSTRACT

The lungs are affected by systemic vasculitides with differing frequency, characteristics, and severity, depending on the specific vasculitis syndrome. Alveolar hemorrhage, nodules, interstitial disease and airway stenoses are the most common lung manifestations of antineutrophil cytoplasm antibody-associated vasculitides. Pulmonary vascular involvement occurs in Behçet disease and Takayasu arteritis, where it manifests as pulmonary artery aneurysm, thrombosis and stenosis. Lung involvement can occur along with other systemic features of vasculitis syndromes but can also be isolated, which leads to diagnostic and therapeutic challenges. Lung infection, pulmonary edema due to cardiac failure or renal impairment, cancer, and drug-induced lung toxicity are potential mimickers of pulmonary involvement in vasculitis. Once a diagnosis has been made, the management of lung disease in patients with vasculitis includes systemic and local therapies.

Keywords: vasculitis, lung, ANCA, AAV

INTRODUCTION

The lungs are affected by systemic vasculitides with differing frequency, characteristics and severity, which vary by type of vasculitis. There can be involvement of the airways, lung parenchyma, intra-parenchymal proximal pulmonary arteries and veins, capillary vessels or

* Corresponding Author's Email: cpagnoux@mtsinai.on.ca; Tel: 416-586-4800 ext. 8549; Fax: 416-586-8766.

pleura. These manifestations can be clinically silent or life-threatening, as with diffuse alveolar hemorrhage. They can occur with other systemic manifestations of vasculitis or, less commonly, in isolation, which creates diagnostic challenges. Treatment should be tailored to the type and severity of the underlying vasculitic process and may combine systemic and local therapies. Lung infection, pulmonary edema due to cardiac failure or renal failure, cancer, and drug-induced lung toxicity can occur in patients with vasculitis.

This chapter focuses on the lung manifestations of systemic vasculitides, as defined by the Chapel Hill Consensus Conference (CHCC) [1], and prophylactic measures to limit the risk of secondary complications.

MAIN LUNG MANIFESTATIONS IN SYSTEMIC VASCULITIS

A broad spectrum of lung manifestations may occur with systemic vasculitis and include alveolar haemorrhage, lung nodules, interstitial disease, airway stenoses, fibrosis, pleural effusion and pneumothorax. These may occur in small-vessel (SVV) antineutrophil cytoplasm antibody (ANCA)-associated vasculitides (AAV) (granulomatosis with polyangiitis [GPA], eosinophilic granulomatosis with polyangiitis [EGPA] and microscopic polyangiitis [MPA]). Lung vessel involvement manifests as pulmonary artery aneurysms, thrombosis and stenoses in the variable vessel vasculitis (VVV) Behçet disease (BD) and the large-vessel vasculitis (LVV) Takayasu arteritis (TAK). The risk of pulmonary embolism increases during disease flares in AAV.

Airway Disease

Nasal, sinus, mouth, throat and the upper airways are commonly involved in GPA leading to chronic erosive sinusitis, crusting rhinitis, nasal septum perforation and subglottic stenosis. Allergic rhinosinusitis, nasal polyposis, lower large- and small-airway disease (asthma) are manifestations associated with EGPA. Tracheo-bronchial stenosis is more characteristic of GPA but can also occur in EGPA.

Tracheo-Bronchial Stenosis

Tracheal and bronchial involvement occurs in up to 70% of patients with GPA. Stenoses of the main bronchus, seen more often the left along the first branches, are observed in less than 10% of patients [2-5]. Subglottic stenosis is the classic large airway lesion and occurs in 7% to 15% of patients with GPA [6-8]. It may cause dysphonia. Like subglottic stenosis, tracheal and bronchial stenoses cause dyspnea, with or without stridor and wheezing. Large airway obstruction occasionally requires emergency dilatation, often combined with local injections of corticosteroids, or tracheostomy. Complete bronchial occlusion can cause partial or complete collapse of the lung distally. Endobronchial lesions can cause hemoptysis if there is mucosal ulceration and erosion of an underlying vessel. Such tracheal and bronchial lesions are best studied with a combination of chest computed tomography (CT) (Figure 1) and direct visualization with fiber-optic bronchoscopy because of possible multifocal involvement with strictures, ulceration and granulomatous endobronchial lesions. These airway lesions can

parallel extra-respiratory manifestations of GPA or may progress despite adequate control of the systemic vasculitis.

Figure 1. Left main bronchial stenosis, visible on bronchoscopy (left image), with beading appearance on axial CT scan (right image).

Asthma

Asthma is a defining feature of EGPA [9, 10] and usually develops before the onset of systemic manifestations of vasculitis. 90% of affected patients have asthma at EGPA diagnosis, but it rarely develops after the initial diagnosis. The interval between onset of asthma and EGPA diagnosis is about 9 years, on average, with a mean age at onset of asthma of 32 years, which emphasizes its relatively late-onset compared to usual asthma. Asthma typically increases in severity in the months to years before the onset of systemic manifestations of vasculitis and persists when the initial vasculitic manifestations occur, even after adequate control of the underlying vasculitis. Many patients require long-term, low-dose prednisone and inhaled corticosteroids for control of airway symptoms despite remission of the systemic vasculitis. Whether the characteristics of vasculitis-associated asthma differ from idiopathic and allergic asthma is not well understood [11]. Spirometric evaluation reveals an obstructive pattern, but no clinical findings or functional tests distinguish among these various causes of asthma. As a rule, late-onset asthma, especially if it is difficult to control and increasing blood eosinophilia should prompt consideration of EGPA.

Parenchymal Disease

Vasculitis-related parenchymal lung disease is common in GPA, MPA, EGPA, and anti-glomerular basement membrane (anti-GBM) disease but also occurs in the LVV giant cell arteritis (GCA) and the SVV immune complex (IC) disorder, Henoch-Schonlein purpura/IgA vasculitis (HSP/IgAV) [12].

Alveolar Hemorrhage

Diffuse alveolar hemorrhage (DAH) is a classical manifestation of AAV and occurs in 12% to 32% of patients with MPA and in 8% to 30% of those with GPA, 60% to 80% of

those with anti-GBM disease (or Goodpasture syndrome), and in less than 10% and 2% with EGPA and IgAV, respectively. The extent and severity of pulmonary capillaritis varies from clinically silent to shortness of breath and subacute to acute fulminant hemoptysis and respiratory distress syndrome. Hemoptysis is absent in up to one third of patients with alveolar hemorrhage, which then is diagnosed by the presence of anemia, patchy ground-glass opacities on chest CT (Figure 2), and persistently bloody returns on broncho-alveolar lavage. In addition to ground-glass opacities, chest CT may reveal alveolar consolidation and localized rather than diffuse or patchy infiltrates. CO diffusion capacity is usually increased when there is blood in the alveoli, but pulmonary function testing (PFT) is rarely indicated or performed in patients with frank alveolar hemorrhage. DAH is frequently associated with renal disease in GPA, MPA and anti-GBM disease and may be part of a pulmonary–renal syndrome. When alveolar hemorrhage occurs as an isolated event or is associated with non-specific constitutional symptoms, diagnoses other than vasculitis should be considered (Table 1) [13, 14]. Hemoptysis from lung capillaritis should be differentiated from other vasculitic causes of bleeding such as submucosal vessel rupture in patients with endobronchial GPA mucosal ulceration or rupture of larger-vessel aneurysms in patients with TAK and BD.

Table 1. Main causes of alveolar hemorrhage

Disease or disease group		Comments
Lung parenchymal disease/inflammation		
<i>Small vessel vasculitis</i>	ANCA associated vasculitis	Mainly GPA and MPA (rarely EGPA)
	Anti-GBM disease	
	Immune-complex mediated vasculitides	Rarely IgA vasculitis (exceptionally, cryoglobulinemic vasculitis)
	Isolated (idiopathic) lung capillaritis	
<i>Other systemic diseases</i>	Systemic lupus erythematosus	
	Antiphospholipid syndrome	
	Rheumatoid arthritis	Through lung disease and/or associated vasculitis
	Systemic scleroderma	Through lung disease and/or associated vasculitis and/or veno-occlusive disease
	Polymyositis/dermatomyositis	
	Sarcoidosis	
<i>Drug-related lung toxicity</i>	Propylthiouracil, diphenylhydantoin, amiodarone, mitomycin, D-penicillamine, methotrexate, gold, haloperidol, nitrofurantoin all-trans-retinoic acid, bleomycin	Most can cause interstitial lung infiltrates rather than diffuse alveolar hemorrhage
<i>Toxic and irritant inhalation</i>	Trimellitic anhydride, isocyanates, crack cocaine, pesticides, detergents	
<i>Miscellaneous</i>	Lung-graft rejection	
<i>Infections</i>	Human immunodeficiency virus infection, infective endocarditis, cytomegalovirus infection, herpes simplex virus infection, hantavirus infection, invasive aspergillosis, legionellosis, mycoplasmosis, leptospirosis, other bacterial pneumoniae	

Disease or disease group		Comments
Not primarily due to lung parenchymal disease/inflammation		
<i>Lung vessel and/or aneurysm rupture</i>	Multiple causes: traumas, vascular malformation or fibrodysplasia, vasculitis-related aneurysms (Takayasu arteritis, Behcet's disease), lung abscess/cavity or bronchial lesions eroding nearby vessels, etc.	
<i>Hemostasis disorders</i>	Thrombotic thrombocytopenic purpura and idiopathic thrombocytopenic purpura, anticoagulants, antiplatelet agents, thrombolytics; disseminated intravascular coagulation	Usually associated with another and underlying lung condition when causing diffuse alveolar hemorrhage
<i>Mitral stenosis and mitral regurgitation</i>		
<i>Pulmonary veno-occlusive disease</i>		
<i>Idiopathic pulmonary hemosiderosis</i>		
<i>Pulmonary embolism</i>		
<i>Malignant conditions</i>	Lung cancer, pulmonary angiosarcoma, Kaposi sarcoma, multiple myeloma, acute promyelocytic leukemia	
<i>Other conditions/ miscellaneous</i>	High-altitude pulmonary edema, barotrauma	
	Lymphangioleiomyomatosis	
	Pulmonary capillary hemangiomatosis	
	Lymphangiography	
	Tuberous sclerosis	

ANCA: antineutrophil cytoplasm antibody; EGPA: eosinophilic granulomatosis with polyangiitis; GBM: glomerular basement membrane; GPA: granulomatosis with polyangiitis; MPA: microscopic polyangiitis.

Figure 2. Diffuse alveolar hemorrhage in a patient with granulomatosis with polyangiitis (left: chest X-ray with diffuse infiltrate; right: diffuse ground-glass opacities and infiltrates on axial CT scan).

Nodules

Lung nodules are a classical feature of GPA but can also occur in EGPA [15]. They can be cavitated, single or multiple, and vary in size and location (Figures 3 and 4). No specific characteristics on chest CT differentiate them from malignancy; tuberculous, nocardial or *Burkholderia* species infections; or lymphomatoid granulomatosis and sarcoidosis (Table 2). Supra-infection of cavitating nodules, notably by *Aspergillus* species, can occur. Surgical tissue biopsy, wedge-resection and CT-guided needle aspiration of nodules in GPA may reveal non-caseating granulomatous and necrotizing inflammation [16-19]. Plain nodules can

become cavitated as a result of central necrosis and evolve into nodular scars that persist beyond remission of vasculitis. They have been inconsistently associated with risks of relapse: over a follow-up of 8.8 years, the presence of cavitary nodules at diagnosis was identified as an independent predictor factor with 53% rate of relapse [20]. Non-active nodules at remission are more often plain than cavitated and smaller, measuring <15 mm in diameter [21].

Table 2. Main differential diagnoses of granulomatosis with polyangiitis with lung nodules

Other vasculitides		Comments
Primary	Eosinophilic granulomatosis with polyangiitis (Churg–Strauss syndrome)	Lung nodules can occasionally occur
	Microscopic polyangiitis	Anecdotal cases with lung nodules
	Giant cell arteritis (temporal arteritis)	Anecdotal cases with lung nodules
	Henoch–Schonlein purpura	Anecdotal cases with lung nodules
Secondary	Relapsing polychondritis	Few cases with lung nodules (possible overlapping diagnosis with GPA)
	Drug-induced (and/or hypersensitivity) vasculitis	Anecdotal cases with lung nodules
	Rheumatoid arthritis	Lung nodules can occasionally occur, with or without associated vasculitis
	Inflammatory bowel disease, systemic lupus erythematosus, systemic sclerosis, primary Sjogren syndrome, etc.	Rare cases with lung nodules
Granulomatous diseases		
	Lymphomatoid granulomatosis (Liebow)	Rare systemic angiodestructive lymphoproliferative disease, usually associated with chronic Epstein-Barr virus infection
	Nasal NK-cell lymphoma	
	Sarcoidosis	
	Berylliosis	
	Inflammatory bowel disease	Rare cases with lung nodules
Infections (not limiting list)		
	Tuberculosis	
	Histoplasmosis	
	Atypical mycobacterial infections	
	Blastomycosis, coccidioidomycosis, actinomycosis, cryptococcosis	
	Nocardiosis, Burkholderia cepacia infection	
	Secondary syphilis	
	Parasitic helminth infections (ascariasis, alveolar echinococcosis, paragonimiasis, Schistosoma mansoni, pulmonary dirofilariasis, larva migrans - toxocarosis)	Can cause lung cysts, potentially mimicking lung nodules
Cancers and hemopathies (not limiting list)		
	Lymphomas	
	Plasmacytoma	
	Carcinoid tumors	
	Lung cancer (all types)	
	Lung metastases	
Other/miscellaneous		
	Pulmonary amyloidosis	Anecdotal cases with lung nodules
	Pulmonary pyoderma gangrenosum	
	Mineral oil (lipoid) pneumonia	
	Benign tumors Fibroma, hamartoma, neurofibroma, blastoma, bronchial adenoma	
	Bronchogenic cysts	Can present like nodules
	Atelectasis (post-infection or -surgery)	Can present like nodules
	Anthracoilicosis	Lung nodules are usually small but can reach 1 cm in diameter and be coalescent in severe cases

Figure 3. Multiple plain lung nodules in a patient with granulomatosis with polyangiitis (axial CT images).

Figure 4. Large cavitation nodule in a patient with granulomatosis with polyangiitis (left: chest X-ray showing hydro-aeric cavity; right: same nodule on frontal CT scan, upper and aeric part of the nodule).

Eosinophilic Lung Infiltrates

Lung infiltrates, corresponding to eosinophilic pulmonary inflammation, occur in up to three quarters of patients with EGPA. On chest CT, they appear as patchy, multifocal, with peripheral ground-glass attenuation; uni-, or bilateral and symmetrical or asymmetrical; and sometimes as transient or migratory areas of consolidation (Figure 5). They may be associated with pleural effusions mimicking chronic eosinophilic pneumonia, although the latter presents most often with homogeneous and peripheral lung infiltrates. Broncho-alveolar lavage or thoracentesis can demonstrate the predominant eosinophilic nature of the abnormality, typical of EGPA, and exclude other diagnoses such as infection and alveolar hemorrhage [22].

Fibrosis

Fibrosis is increasingly recognized complication of AAV, mainly anti-MPO AAV. Most often the interstitial pneumonitis and fibrosis preferentially involves the lung bases (Figure 6). Interstitial lung disease (ILD) can either occur after onset or precede the onset of full vasculitis by years [23-25]. The pathogenic mechanism of ILD is not well understood but may relate to oxidative bursts of inflammatory cells triggered by ANCA, along with damage resulting from recurrent or chronic alveolar hemorrhage [26-28]. Usual interstitial pneumonia (UIP) is the most common radiologic pattern [25]. The mortality rate of pulmonary fibrosis with anti-MPO P-ANCA, mainly related to respiratory failure, is similar to that of idiopathic

pulmonary fibrosis and worse than ILD occurring with collagen vascular diseases without anti-MPO ANCA [24, 29].

Figure 5. Patchy lung alveolar interstitial infiltrates in a patient with eosinophilic granulomatosis with polyangiitis (frontal and axial CT images).

Figure 6. Massive lung fibrosis in a patient with anti-MPO-ANCA vasculitis in remission (frontal and axial CT images), with honeycombing appearance.

Non-Specific Pulmonary Consolidation

Pulmonary consolidation and infiltrates mimicking infectious pneumonia can be observed in GPA, MPA and EGPA. Diffuse interstitial lung infiltrates can be seen in GCA, TAK, IgAV, BD and cryoglobulinemic vasculitis (CV) [12, 30, 31]. ILD and alveolar hemorrhage due to pulmonary capillaritis can also occur in rheumatoid-associated vasculitis (RAV), or with systemic lupus erythematosus (SLE).

Pleural Effusion and Pneumothorax

Pleural effusions are common in EGPA and polyarteritis nodosa (PAN). They can be inflammatory or related to cardiac or renal failure. They may also be due to pulmonary embolism, which is more frequent during disease flares. Pneumo- and hydro-pneumothoraces can be caused by the outward progression of peripheral lung nodules that involve the pleura and cavitate, leading to development of bronchopleural fistula [32, 33].

Pulmonary Embolism

Patients with AAV and to a lesser extent, medium-vessel vasculitis (MVV) such as PAN, are at increased risk of venous thromboembolic events, including pulmonary embolism, during the active phase of the vasculitic disease [34, 35]. In BD, pulmonary embolism can be due to right ventricular thrombi related to increased tissue-factor expression, neutrophilic extracellular traps and neutrophil-derived micro-particles [36]. Anti-PR3-ANCA antibodies with dual reactivity to plasminogen and complementary PR3 may be pathogenic in thrombosis in GPA [37].

Pulmonary Artery Stenosis and Aneurysms

The pulmonary arteries are involved by the vasculitic process in LVV and BD and exceptionally in other vasculitides [38]. Stenoses and aneurysms of the main pulmonary arteries can occur (Figure 7). Dilations of single, multiple, unilateral and bilateral pulmonary and bronchial arteries occur in less than 5% of patients with BD referred to as Hughes-Stovin syndrome [39]. Affected patients are typically men with a history of thrombophlebitis. Pulmonary and bronchial artery aneurysms can rupture, thus leading to hemoptysis and internal haemorrhage, or demonstrate progressive occlusion with thrombosis.

Figure 7. Main right pulmonary artery stenosis in a patient with Takayasu arteritis (CT-angiography, frontal reconstruction and axial image).

Pulmonary Hypertension

There are anecdotal reports [40, 41] of pulmonary hypertension in patients with TAK, PAN and AAV. Secondary pulmonary hypertension can result from pulmonary artery involvement, constrictive pericarditis, restrictive cardiomyopathy, or lung fibrosis [42]. Chronic thrombo-embolism can lead to pulmonary hypertension and should be actively considered as it is treatable.

Phrenic Palsy

Unilateral phrenic palsy due to mono-neuritis multiplex can occur in GPA and EGPA [43, 44]. However, it can be co-incidental, related to pre-existing conditions including trauma, or due to an unknown and unrelated cause.

LARGE-VESSEL VASCULITIDES

Parenchymal lung manifestations occur so rarely in LVV that when present, should prompt review of the diagnosis of vasculitis or consideration of a co-existing condition. However, involvement of pulmonary arteries can be an expected feature of LVV, especially in TAK.

Giant Cell Arteritis

One-quarter of patients with GCA have a dry, non-productive cough. Less common manifestations include alveolar hemorrhage, T-CD4⁺ lymphocytic alveolitis, pleural effusion and thickening, multiple pulmonary infarctions, lung nodules and ILD [45-48].

Takayasu Arteritis

TAK can involve the pulmonary arteries, although less frequently than the aorta or other arteries with stenoses, with or without dilations (Figure 7). The involvement can be associated pulmonary hypertension, lung infarction, arterial rupture and hemorrhage, regional hypoperfusion, and lung ventilation and perfusion mismatching suggestive of pulmonary embolism. There may be lung nodules, parenchymal consolidation, sub-pleural reticulo-linear changes, pleural effusion and thickening, pulmonary-renal syndrome, and ILD [49-56].

MEDIUM-VESSEL VASCULITIDES

Pulmonary artery and less often parenchymal involvement can occur in MVV.

Polyarteritis Nodosa

The lung parenchyma is not typically affected in PAN and the occurrence of capillaritis with alveolar hemorrhage should raise doubt about the diagnosis of PAN or question the possibility of an underlying genetic disease such as STING-associated vasculopathy [57]. Prior to the 1994 CHCC [58], patients presenting purpura, hemoptysis, and pulmonary hemorrhage that preceded the explosive phase of systemic necrotizing vasculitis affecting the

kidney and lungs with rapidly progressive glomerulonephritis and pulmonary capillaritis were considered to have a microscopic form of PAN. This condition was later considered a separate category of SVV, termed MPA [59]. Pulmonary edema and pleural effusion in PAN are usually due to renal and/or cardiac insufficiency. Patients with PAN can present with interstitial pneumonia, lung nodules and cavitary lesions. Although clinical and angiographic bronchial artery involvement is considered uncommon, seven of ten patients were found to have bronchial arteritis on post-mortem examination [60-62], so this manifestation of vasculitis may be under-recognized.

Kawasaki Disease

Children with Kawasaki disease (KD) often develop respiratory symptoms due to upper-respiratory tract inflammation. Affected children may present with pneumonia, and up to 15% show lung consolidation on chest radiography within 10 days of illness onset. Other radiographic abnormalities include peri-bronchial cuffing, pleural effusion, atelectasis and air trapping [63]. The incidence of coronary artery lesions is greater in patients with abnormal chest radiographs. Interstitial micro-nodular infiltrates and larger inflammatory pulmonary nodules can occur [64-68].

SMALL-VESSEL VASCULITIDES

Parenchymal and airway disease occur more commonly in SVV than MVV and LVV. Alveolar hemorrhage is the hallmark of GPA, MPA and EGPA; lung nodules and bronchial stenosis are more characteristic of GPA, and asthma is most consistent with EGPA [69].

Granulomatosis with Polyangiitis

Overall, 70% to 100% of patients with GPA show lung involvement, with clinical manifestations ranging from mild cough, dyspnea, chest pain, and intermittent hemoptysis to acute respiratory distress syndrome and massive alveolar hemorrhage. In 6% of patients, lung involvement remains asymptomatic, especially with lung nodules. Tracheobronchial involvement, including subglottic stenosis, ulcerating tracheo-bronchitis and sometimes endobronchial stenoses, can be seen in 17% of patients [70]. Subglottic involvement seems to be more common in the pediatric-onset GPA compared with the adult population, occurring in up to 41% of cases [71]. Although not specific, lung nodules are among the most characteristic involvement, and are present in 40% to 66% of patients with GPA, occurring as ≤ 10 in number, unilateral, bilateral, and single or multiple lesions [20]. Half of them may cavitate, especially when larger than 2 cm [72]. The differential diagnosis of lung nodules remains wide, and should include primary and metastatic tumors, sarcoidosis, tuberculosis and fungal infections (Table 2). Alveolar hemorrhage, the most feared manifestation, is usually secondary to capillaritis and is noted in 18% to 30% of patients with GPA. It can occur at disease onset or later in the course signaling relapse of the disease [20, 73]. It may

appear as ground-glass opacities surrounding pulmonary nodules. In all, 30% to 50% of patients show other pulmonary infiltrates or lung consolidations, and 9% to 28% show pleural effusion. Spontaneous pneumothorax and empyema can occur, sometimes related to nodule cavitation and rupture. Pulmonary embolism may indicate active GPA and systemic inflammation. All patients with acute presentation of GPA should undergo chest CT/HRCT, because small nodules, alveolar hemorrhage and other lesions may be missed on chest radiography. Even when the diagnosis of GPA is clinically apparent, broncho-alveolar lavage should be considered to exclude concurrent infection and clinically silent alveolar hemorrhage. Surgical lung biopsies, targeting nodules and consolidated lesions, have a diagnostic yield of 76% to 91% [3, 74]. Transbronchial biopsies are seldom positive, unless performed on a macroscopically abnormal lesion. Transbronchial cryobiopsy and video-assisted thoracoscopic biopsy are other possible diagnostic options [75].

Microscopic Polyangiitis

Alveolar hemorrhage and pulmonary–renal syndrome can be observed in MPA [59, 76, 77]. Arteritis with intimal thickening and focal destruction of the internal elastic lamina and sub-intimal fibrous scarring of the media are typical histological features in diagnostic tissue biopsy specimens. Diffuse alveolar damage and pulmonary fibrosis (Figure 6) can complicate MPA, mainly in patients with anti-MPO P-ANCA MPA. In patients with established idiopathic pulmonary fibrosis, MPO-ANCA positivity may be present in up to 5%. Seroconversion from negative to positive anti-MPO during follow up can be found in up to 15% of patients [78, 79]. The risk of developing systemic vasculitis over time is greater in MPO-ANCA positive patients than those with negative ANCA, and can be as high as 22% [78]. Additionally, pulmonary fibrosis and vasculitis may have independent outcomes, with progression of the fibrosis despite treatment and sustained good control of the vasculitis [24–26, 29]. There is little data on the role of immune suppressing therapies and anti-fibrotic therapies such as pirfenidone and nintedanib in MPO-positive IPF and MPA with pulmonary fibrosis.

Eosinophilic Granulomatosis with Polyangiitis

This rare pulmonary and systemic SVV with an annual incidence of 0.5 to 6.8 per million and a prevalence of 10.7 to 14 per million, develops through three prototypical successive phases. The prodromal phase begins with asthma and allergic manifestations, followed by tissue eosinophilia affecting visceral organs such as the lung and myocardium, and later development of vasculitic features primarily affecting the skin and peripheral nerves. The preponderance of Th2 lymphocytes and eosinophils suggests their participation in the pathogenesis of EGPA. However, ANCA production is noted in up to 40% of patients, which suggests a role in amplifying or facilitating the development of vasculitic lesions. Asthma is a predominant feature in EGPA, present in up to 91% of cases at diagnosis [9]. Lung infiltrates were reported in 39% of patients in the largest series (and up to 72% in a smaller previous series) [9, 80], presenting as multifocal peripheral consolidation in two-thirds of patients, with

unilateral or bilateral, and symmetrical or asymmetrical appearance [81]. A centri-lobular perivascular dense pattern with scattered centri-lobular nodules measuring 5 mm within ground-glass opacities is often found. Multiple large nodules may occur, with occasional cavitation; however, alveolar haemorrhage is rare in EGPA, occurring in less than 5%. Non-compressive mediastinal or hilar adenopathy may also be detected on chest CT. Pleural effusions are present in 9% to 30% of patients and are typically exudative and rich in eosinophils [9].

Anti–Glomerular Basement Membrane Disease

Anti-GBM disease, which was included in the revised 2012 CHCC [1] under the SVV category of IC diseases, typically affects young people, aged 15 to 35 years. Isolated glomerulonephritis occurs in 20% to 40% of patients and is combined with alveolar hemorrhage in 60% to 70% of patients. Isolated alveolar hemorrhage is a rare but described presenting feature of anti-GBM. Alveolar hemorrhage is strongly associated with smoking [82, 83]. Up to one third of patients with anti-GBM disease become ANCA positive at some time during their illness. Such patients have intermediate prognosis with worse renal prognosis than those with isolated AAV.

Other Small-Vessel Vasculitides

Alveolar hemorrhage occurs in less than 5% of patients with IgAV [30] and mixed CV. Other lung manifestations may be due to co-incident human immunodeficiency virus (HIV) or hepatitis C virus (HCV) infection, or a lymphoproliferative disorder.

VARIABLE VESSEL VASCULITIDES

Behçet Disease

Lung manifestations occur in less than 10% of patients with BD [84-89]. Pulmonary artery involvement is most common after aortic involvement in young men with aneurysms and thrombosis, with or without associated aneurysm or vascular stenosis [90, 91]. Clinically, it can remain silent, or present with hemoptysis. Other symptoms of pulmonary artery involvement are cough, fever, pleuritic chest pain and dyspnea [86]. Patients should be systematically screened for aneurysms, which can be seen on chest radiographs, but are best visualized by chest CT and magnetic resonance imaging (MRI). They can be multiple, unilateral or bilateral, with varying diameter, usually 1 to 7 cm. Pulmonary artery involvement is associated with poor prognosis, with mortality exceeding 25% after 7 years of follow-up. Aneurysms can rupture, causing catastrophic hemorrhage or lead to thrombosis with later pulmonary hypertension and lung infarction. Most patients have concomitant extra-pulmonary venous thrombi and thrombophlebitis (Hughes-Stovin Syndrome). A pulmonary aneurysm justifies treating with cyclophosphamide and high-dose corticosteroids. Consensus

is lacking on the role of anticoagulant and antiplatelet therapies as they may be associated with massive hemorrhage and mortality risk. Surgery, embolization, and endovascular procedures should be considered in combination with systemic therapy because of the complications associated with active vasculitis. Atelectasis, nodular, or reticular opacities and cavities can occur, corresponding to foci of pulmonary hemorrhage, infarction, and diffuse alveolar hemorrhage due to SVV. Secondary organizing pneumonia, pleural nodules or effusions resulting from vasculitis of the pleura or thrombosis of the superior vena cava, ulcerative lesions of the trachea and/or proximal bronchia as well as mediastinal lymphadenopathy can also occur. Pulmonary embolism in BD is rare and most often due to local pulmonary artery thrombosis rather than embolic peripheral venous thrombosis.

Other Vasculitides

Lung manifestations occur in patients with lupus vasculitis, RAV, sarcoidosis, systemic scleroderma, HCV infection, and illicit use of substances such as cocaine [92-96]. Alveolar hemorrhage due to capillaritis in SLE is similar to what is observed in MPA. Different pathogenic mechanisms may be involved in the development of ILD and lung nodules in RAV. Cocaine and levamisole-tainted cocaine induce lung complications including a GPA-like syndrome with skin, nasal sinus involvement and lung-nodules rather than alveolar hemorrhage. ANCA-seropositivity can be present as well as ELISA findings of specificity to PR3 and various patterns on indirect immunofluorescence [97, 98].

TREATMENT AND PROGNOSIS

Before initiating therapy for pulmonary manifestations, the treating physician should be certain that other conditions, especially infections, cancers, and drug toxicity, are not mimicking pulmonary vasculitis. These conditions may co-exist with active vasculitis, such as supra- or opportunistic infection of a lung cavity with *Mycobacteria* and *Aspergillus* species or cancer leading to paraneoplastic syndrome [99, 100]. Treatment should be individualized to the vasculitis identified, its severity and the type of organ involvement. Although lung manifestations in AAV do not necessarily confer poorer prognosis, alveolar hemorrhage and tracheo-bronchial stenoses warrant aggressive management to avert excess morbidity and mortality. It has been demonstrated that rituximab was as effective for induction therapy as cyclophosphamide in diffuse alveolar hemorrhage in the rituximab in ANCA-Associated Vasculitis (RAVE) trial, although patients requiring mechanical ventilation were excluded from this trial [101]. Conversely, the preliminary results of the large, controlled PEXIVAS study [102] suggested that plasma exchange did not improve survival in patients with severe diffuse alveolar hemorrhage, as opposed to reports from a few small case series or case-control studies [103]. Systemic treatment is often disappointing in subglottic and bronchial stenoses. Endoscopic dilations with bougies, balloons and repeated local injection of corticosteroids with or without mitomycin application may be effective. Tracheal stents and surgery should be considered only in refractory disease. Patients with GPA and lung nodules, without any other threatening systemic manifestations or major organ

involvement, can be managed with less toxic drugs such as methotrexate. The optimal treatment strategy for lung fibrosis and ILD remains to be determined.

Consensus is lacking on the optimal clinical and laboratory monitoring of patients with vasculitis and lung manifestations, but repeated chest radiographs and PFTs at 3 to 6-month intervals earlier in the disease seem reasonable. Repeat CT, because of radiation concerns, should be reserved to resolve uncertainties or to evaluate response to treatment, complications or new manifestations of disease. The intensity of follow-up would vary, depending on the severity of the lung lesions and the impairment of function as well as the presence of subglottic and bronchial stenotic lesions which require direct visualization at bronchoscopy.

CONCLUSION

Lung manifestations are common in several vasculitides and can present various features, some of them potentially life-threatening. After exclusion of conditions mimicking vasculitis, treatment with systemic and local therapies can be initiated with the expectation of improvement. In the longer term, complications of treatment can be as troublesome as complications of the disease. Identification of effective, less toxic and optimal combinations of therapies for the most severely affected patients, and those with chronic lung complications such as anti-MPO-ANCA-associated pulmonary fibrosis, and others with AAV will be clarified by emerging evidence from clinical trials.

ABSTRACT

Systemic vasculitides affecting small- and medium-sized vessels are particularly likely to involve the kidneys. These vasculitides include microscopic polyangiitis, granulomatosis with polyangiitis, and eosinophilic granulomatosis with polyangiitis, IgA vasculitis, polyarteritis nodosa, and cryoglobulinemic vasculitis. The most common culprits of kidney injury in adults are microscopic polyangiitis, granulomatosis with polyangiitis, and eosinophilic granulomatosis with polyangiitis, which predominantly affect small vessels and are typically associated with the presence of anti-neutrophil cytoplasmic autoantibodies. For this reason, we focus here on anti-neutrophil cytoplasmic autoantibody-associated vasculitides. Over the past three decades, tremendous progress has been made through investigative efforts to understand etiologic, pathogenetic and clinical underpinnings of these disorders. We highlight notable findings that represent key breakthroughs in the field and proceed to the clinical presentation, diagnosis, and an up-to-date discussion of studies related to clinical management for inducing and maintaining remission. Finally, we review key prognostic indicators of renal outcomes and predictors of treatment resistance and relapse. Although these diseases have been transformed from ones that were usually fatal to ones that are now chronic with potential

for long-term and symptom-free remission, many challenges remain to decrease diagnostic delays, increase our understanding of molecular mechanisms of genetic and environmental risk factors for disease, and further refine and personalize treatment strategies that maintain remission and minimize treatment-related morbidity.

Keywords: ANCA, vasculitis, kidney

INTRODUCTION

Many forms of systemic vasculitis directly affect the kidneys, and resultant injury can lead to chronic kidney disease and even end-stage kidney disease. Vasculitides affecting small- and medium-sized vessels are particularly likely to involve the kidneys. They include polyarteritis nodosa (PAN), IgA vasculitis (IgAV, formerly Henoch-Schönlein purpura), microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA, formerly Wegener granulomatosis), eosinophilic granulomatosis with polyangiitis (EGPA, formerly Churg-Strauss syndrome), and cryoglobulinemic vasculitis. The most common causes of kidney injury among this group are IgAV in children; and MPA, GPA, and EGPA in adults. MPA, GPA, and EGPA affect predominantly small vessels, and are often, although not always, associated with the presence of antineutrophil cytoplasmic autoantibodies (ANCA). Given their predilection for kidney involvement, further discussion in this chapter will focus primarily on these ANCA-associated vasculitides (AAV).

EPIDEMIOLOGY

Most data on the incidence and prevalence of AAV derive from studies in Caucasian populations of European descent, although there are also emerging data from Asia and parts of the Middle East. Disproportionate reporting in Caucasians may reflect case ascertainment bias, availability of diagnostic resources, or high prevalence of competing diagnoses, for example, tuberculosis in the case of granulomatous disease, rather than true difference. However, data from multi-ethnic populations suggest that there are true differences in disease incidence based on geographical location, ethnicity, or race, or a combination thereof. As an example, a study of a multi-ethnic population in a Paris suburb, 28% of who were of non-European ancestry, found that the overall prevalence of AAV, as well as PAN, in Europeans was twice that observed in non-Europeans [1]. Similar ethnic differences are seen in New Zealand, where Europeans appear to have a much higher annual incidence of AAV of 60.2 cases per million individuals than the indigenous Māori population with 34.2 cases per million individuals [2]. The annual incidence in Pacific Peoples in New Zealand of 17.26 cases per million individuals was also lower than that of Europeans.

The average incidence of AAV in Japan appears to be similar to that in the United Kingdom (UK), with 22.6 and 21.8 cases per million individuals annually, respectively, [3] however, with notable differences. In Japan, the vast majority (83%) of patients has MPA and is MPO-ANCA positive. Conversely, 66% of patients in the UK have GPA, and a similar number are proteinase 3 (PR3)-ANCA positive. Interestingly, kidney involvement was noted

to be less common in patients with GPA in Japan than in the UK. AAV is also recognized in China [4] and India [5], as well as regions of the Middle East [6], but there are no data regarding incidence and prevalence in these areas. In a study on distribution of ANCA types, MPO-ANCA was more common than PR3-ANCA in the Chinese patients (OR 6.8, CI 2.6-17.8) [7]. Though AAV is uncommon in Africans, there are rare case reports of AAV from Africa [8]. African Americans are more often MPO-ANCA positive (71% vs. 54%, $p = 0.01$) and younger at diagnosis (52 versus 57 years), when compared to Caucasians [9]. However, treatment response, ESRD, renal relapse, and death were similar between the two groups [9]. It is important to note that while PAN, a medium-vessel vasculitis, is not classified as an AAV; it has historically been included in most of these data. Collectively, there is believed to be an overall incidence of approximately 10 to 20 cases per million individuals annually in Caucasian patients of European descent [10]. The prevalence of AAV is approximately 46 to 184 cases per million individuals [11].

Strikingly, multiple examples exist of differences in incidence of AAV that appear to be dependent upon geographic milieu. For example, in northern Saskatchewan, Canada, a 2.69 odds ratio (OR) of developing AAV was reported in a rural versus urban setting [12]. A study from the Australian Capital Territory of New South Wales found the annual incidence of MPA to be significantly higher in rural versus urban areas (13.9 vs 1.6 cases per million individuals), with a similar trend seen in the incidence of GPA [13].

There are also multiple reports that demonstrate differences in incidence relative to latitude. A north-to-south positive gradient was observed in the Southern Hemisphere, and a south-to-north positive gradient is seen in the Northern Hemisphere. In other words, incidence of AAV appears to correlate with latitudinal equatorial proximity. This association was apparent in one study from New Zealand [2], located in the Southern Hemisphere, where an increase in incidence of GPA was noted moving from north to south. A second study comparing incidence of AAV in two regions of Europe, including Norwich, UK, latitude 52°N; and Lugo, Spain, 43°N, both in the Northern Hemisphere, found a higher incidence of GPA in Norwich, the more northerly latitude, than in Lugo, even though the overall incidence of AAV was nearly identical [14]. Interestingly, no such difference has been noted in MPA or EGPA. Similar observations regarding incidence relative to latitude have been reported elsewhere [15]. The incidence of AAV is similar in males and females, and the average age of disease-onset varies somewhat within populations, but occurs predominantly in the sixth and seventh decades of life. The relationship of disease to this demographic may be somewhat skewed since, when evaluated retrospectively, a number of patients arguably had evidence of disease years prior to diagnosis. Diagnostic delays are well-substantiated in the literature [16, 17]. Furthermore, most studies of disease do not include pediatric patients, and it is important to remain cognizant that AAV can occur at any age [18-20].

PATHOGENESIS

Since the initial discovery of AAV and glomerulonephritis [21], incredible strides have been made in understanding the etiology and pathogenesis of these diseases. From a fundamental point of view, for autoimmunity to occur, there needs to be a break in self-tolerance to autoantigens. The three major phases of autoimmunity in a susceptible individual

include initiation, propagation and resolution [22]. Genetic susceptibility and environmental factors including many infections are common initial triggers. Molecular mimicry and autoantigen complementary to a bacterial peptide are some of the mechanisms responsible for origination of ANCA production. HLA can bind peptides, from self- or non-self-antigens and present it to T cells for initiation of immune activation. Among other genetics associations, a strong link has been found between HLA genetic regions and AAV [24].

Along with continuous antigen exposure, a defect in regulatory machinery of immune response, T regulatory cells (Tregs) and B regulatory cells results in propagation of the disease process. Although the mechanism still needs to be defined, multiple studies have shown involvement of persistently activated T cell effector arm of the adaptive immune system [23]. A balance between Tregs/effector cells is essential to prevent autoimmunity. FOXP3 is a major transcriptional factor for CD4⁺ Tregs; in active AAV, these Tregs, due to use of a splice variant of FOXP3, are unable to suppress effector CD4⁺ T cells, thus playing an important role in the propagation of autoimmunity [25]. Also, B cells with regulatory function (with high CD5 expression) are decreased in active AAV and increased during remission [26].

Various *in vitro* observations have established that ANCA can bind to cytokine-primed neutrophils, resulting in its degranulation, respiratory burst and efflux of the proteinases. In addition, upon activation, neutrophils can release proinflammatory cytokines, resulting in augmentation of inflammatory cascade. Both MPO and PR3 are cytoplasmic antigens, priming with cytokine results in its expression on cell surfaces. ANCA bind to FcγR expressed on neutrophil and F(ab')₂ segment binds to MPO/PR3 antigen on the cell surface leading to neutrophil activation [27-29].

The pathogenicity of IgG ANCA comes from different observations, clinical, *in vitro* and from animal models. The majority of patients with pauciimmune necrotizing crescentic glomerulonephritis have positive ANCA serology, but its titer does not always correlate with disease severity, remission or relapse. The first true clinical record depicting the pathogenicity comes from a case of transplacental passive transfer of anti-MPO IgG from a mother with MPA to her neonate, resulting in pulmonary hemorrhage and renal dysfunction [30]. Both clinical hints and *in vitro* results are only suggestive, but to prove the pathogenicity of IgG ANCA, one strives to fulfill Koch's postulates as established by our group in an animal model: (1) immunization of MPO knockout mice MPO^{-/-} with purified mouse MPO in complete Freund's adjuvant resulting in development of anti-MPO antibody; (2) anti-MPO splenocytes containing B and T lymphocytes; (3) injection anti-MPO IgG causes pauci-immune crescentic glomerulonephritis in immune deficient Rag2^{-/-} mice and also wild type mice; and (4) adoptive transfer of anti-MPO splenocytes into Rag2^{-/-} resulted in a severe phenotype of vasculitis in a dose-dependent manner [31]. This demonstrates that anti-MPO antibody itself is sufficient to cause disease, but the severe phenotype seen in the adoptive transfer model is possibly due to synergistic effects of anti-MPO T lymphocytes. Studies on bone marrow transplantation approach showed that bone marrow-derived cells, neutrophils and monocytes were necessary and sufficient for induction of disease by anti-MPO antibody [32]. Systemic administration of bacterial LPS in an animal model caused enhanced circulating TNF-α resulting in severe phenotype of crescentic glomerulonephritis induced by IgG MPO [33]. In addition, due to unknown factors, there is evidence of activation of alternate complement pathway, priming of neutrophils by C5a by binding to C5aR results in

augmentation of inflammatory pathways [34]. The observations from *in vivo* and *in vitro* studies stems the therapeutic tree in AAV, from use of cyclophosphamide, which suppresses both B cell and T cell effector function, to more specific B cell therapy with anti-CD20 monoclonal antibody.

Silica

Noted geographical differences in incidence may imply that environmental and other geo-local triggers play a role in disease development. Silica has been implicated as one such trigger. The first account of a possible association of silica with autoimmune disease was a 1914 report of systemic sclerosis occurring in Scottish stonemasons [35]. There have since been a number of studies correlating silica exposure with the development of other autoimmune diseases, particularly rheumatoid arthritis (RA) [36], but also systemic lupus erythematosus (SLE) [37-39]. Data regarding the latter are conflicting [40], but differences in results may reflect dissimilarities in study methodology and patient characteristics. Data on the contribution of silica to the development of AAV have been inconsistent. A study of 2,288 patients from Sweden found no statistically significant association between an occupation and development of GPA, although borderline associations were seen in miners, paper workers, bakers, and animal keepers [41]. However, a meta-analysis of six case-control studies examining silica exposure and risk of AAV found an overall significant summary effect of silica exposure (summary OR 2.56; 95% confidence interval [CI] 1.51-4.36) with development of AAV [42]. This summary OR was similar to the OR seen in studies looking exclusively at either MPA (OR 3.95, 95% CI 1.89-8.24) or GPA (OR 3.56, 95% CI 1.85-8.82).

Difficulties in comparing studies like these have been due largely to study heterogeneity, with studies using different methods for ascertaining silica exposure. Negative studies have been quite large numbering up to 2,288 patients, whereas positive studies have generally been small, ranging from 16 to 129 patients, with variable inclusion criteria. For example, one study included only men [43], while others differed in the age range of patients included. All but one study [44] included only patients with glomerulonephritis, with or without other organ system involvement. Determination of ANCA seropositivity by immunofluorescence (IF) enzyme-linked immunosorbant assay (ELISA) or a combination thereof varies in the literature with one study including 3 patients who were ANCA seronegative [45]. The duration of exposure to potential silica-containing compounds, as well as the time from exposure to clinically-evident disease has varied. However, the degree of silica exposure, which included both duration and intensity of exposure, was found to be significant in a case control study of biopsy proven glomerulonephritis caused by AAV [46]. High lifetime silica exposure was associated with development of AAV when compared to none (OR 1.9, 95% CI 1.0-3.5, $P = 0.05$). No study of silica exposure included patients with pulmonary- or otolaryngologic-limited disease, even though exposure is likely through inhalation of crystalline particulates. However, in terms of exposure risk, the study by Hogan and coworkers [40] did not find significant differences in patients with and without pulmonary involvement. The geographical region of either study could have contributed to the variable results.

Despite data inconsistencies, silica is generally accepted as having a potential role in the development and perpetuation of AAV. Mechanisms by which silica may promote autoimmunity have not yet been fully elucidated. One study of silica-exposed workers in Brazil [47] found increased levels of soluble interleukin-2 receptor (sIL-2R), thought to reflect increased immune activation in these individuals. However, investigators did not specifically consider the role of silica in autoimmunity. Another study of slate miners demonstrated increased and chronic T-cell activation in patients with silicosis either with or without autoimmune disease, including one with pauci-immune glomerulonephritis [48], and found proliferation of peripheral blood mononuclear cells (PBMC) to be 45% higher in cell cultures of silica-exposed patients than in healthy controls. Patients had elevated levels of both pro-inflammatory (interleukin [IL]-1 β , IL-6, tumor necrosis factor [TNF]- α , interferon [IFN]- γ) and anti-inflammatory (IL-10, tumor growth factor [TGF]- γ) cytokines. Chronic T-cell activation was observed in cultured PBMC of silicosis patients in Japan [49]. In particular, activation of T responder cells (Tresp) resulted in later entry into the peripheral CD4+25+ population, whereas activation of FoxP3+ regulatory T-cells (Treg) led to more rapid and higher levels of apoptosis. The net effect was reduced inhibitory function. Silica may also contribute to immune dysregulation by increasing oxidative stress, as suggested by a study of denim sandblasting workers with silicosis in Turkey [50]. Patients had a 1.4-fold higher level of superoxide dismutase (SOD), a possible marker for increased reactive oxygen species generation in these patients [50]. Another study showed decreased L-selectin expression in workers with >16 years of occupational silica exposure, and associations with inflammatory and oxidative stress biomarkers [51]. More recently, neutrophil extracellular traps (NETs) have been implicated in the pathogenesis of AAV [52, 53]. These NETs are involved in trapping silica and have been postulated to trigger autoantibody production by exposing neoantigens [54].

Taken together, these data suggest a somewhat generalized disruption in immune homeostasis in silica-exposed individuals. However, studies to date have not specifically addressed the mechanisms by which silica may cause or promote disease in AAV. By extrapolation, silica is more likely to have an adjuvant effect in patients with predisposition to AAV rather than to be a primary trigger.

Infection

Wegener considered infection as a potential factor in the cause of GPA in the first half of the 20th century [55]. Since then *Staphylococcus (S.) aureus* has received particular attention. The first study comparing the rates of GPA relapse with carriage of *S. aureus* found that 36 of 57 (63%) patients were chronic carriers of *S. aureus*, and analysis demonstrated an adjusted relative risk (RR) for relapse of 7.16 (95% CI 1.63-31.50) independent of other factors [56]. A 2008 study of Polish patients with limited disease [57] found that 17 of 28 (60%) patients were chronic nasal carriers of *S. aureus*, independently conferring a relative hazard risk (HR) for relapse of 4.56 (CI 2.45-7.65). A third study compared nasal carriage of *S. aureus* in patients with GPA to those with rheumatoid arthritis (RA) and chronic rhinosinusitis with nasal polyps (CRS), as well as to hospital staff and subjects without regular exposure to a hospital environment, noting that 72% of patients with GPA had *S. aureus* nasal colonization,

versus 28% of those with CRS, and 25% of patients without regular hospital exposure [58]. Patients with RA and hospital workers had *S. aureus* carriage rates of 46% and 58% respectively, but the differences were statistically insignificant. Colonized GPA patients had significantly higher rates of endoscopically-proven endonasal activity, with more frequent upper respiratory tract involvement at first presentation, and with significantly higher relapse rates compared to uncolonized patients. The use of prophylactic antibiotics, such as prophylactic trimethoprim/sulfamethoxazole, to reduce the relapse risk by decreasing carrier rates is controversial [59-61]. In a 2017 study of AAV [59], the relapse rates for GPA were higher for chronic nasal carriers of *S. aureus*, and prophylactic trimethoprim/sulfamethoxazole reduced the number of carriers (OR 0.19, 95% CI 0.04-0.91, $P = 0.04$). However, in this study, prophylactic trimethoprim/sulfamethoxazole itself did not reduce the relapse risk (OR 0.71, 95% CI 0.36-1.41, $P = 0.33$).

The mechanism(s) by which infection may incite disease has not been fully elucidated, but early investigations have yielded intriguing possibilities. Molecular mimicry, which leads to cross-reactivity of antibodies to both pathogen-derived and self-antigens with substantial structural homology, has been implicated as one of the etiopathogenic factors in AAV. Such cross-reactivity has been observed in several other diseases; streptococcal M proteins and cardiac myosin, as well as other proteins, cross-react in rheumatic fever [62, 63]; *Campylobacter jejuni* epitopes and peripheral gangliosides cross-react in Guillain-Barré syndrome [64]; and Epstein Barr virus epitopes and *Mycobacterium avium paratuberculosis* cross-react with myelin basic protein in multiple sclerosis [65]. A peptide or protein homologous to complementary PR3 (cPR3), transcribed and translated from the antisense strand of *PRTN3* DNA, is thought to be an inciting antigen in a subset of patients with PR3-ANCA disease. In those who are predisposed, antibodies are generated to cPR3. Anti-idiotypic antibodies, or antibodies to anti-cPR3 antibodies, are then produced that are reactive to PR3 [66, 67]. Complementary PR3 shows homology with proteins of multiple microorganisms, including two proteins found in *S. aureus*, thus suggesting a role for molecular mimicry in the pathogenesis of AAV. While PR3-ANCA and MPO-ANCA patients may have the same type of *S. aureus* as the general population, they do have different distributions of clonal complexes [68]. Given recent reports of *S. aureus* proteins binding MPO and/or PR3 antigens, it is postulated [61, 69] that this bacterial protein-autoantigen complex is then internalized and processed by B-cells and then presented to T-cells. This could account for antibody production by B-cells and role of T-cells in ANCA.

Although it remains highly controversial, lysosome-associated membrane protein 2 (LAMP-2) has been identified as a possible antigenic target in patients with AAV [70]. The P₄₁₋₄₉ epitope of LAMP-2 reportedly has significant homology with an epitope of FimH, having in common 8 of 9 amino acids [71], but these findings were not subsequently confirmed [72].

Illicit and Prescription Drugs

Both illicit and prescription drugs have been implicated in the cause of AAV, but the etiopathogenic mechanisms are not well understood. The ant-helminthic agent levamisole, sometimes found in cocaine, is the most recognized drug cause of vasculitis. Affected patients

[73, 74] are typically MPO-ANCA positive, but may have dual positivity with MPO- and PR3-ANCA [73, 74], and typically present with cutaneous disease. While cutaneous disease in idiopathic AAV typically manifests as recurring crops of purpuric lower extremity lesions, the lesions associated with levamisole are more widespread and variable in character, with necrotic lesions involving the ears, and bullous purpura in any location. Full-thickness, large necrotic lesions are suggestive of levamisole exposure. Affected patients can have arthralgia, particularly of the large joints, and constitutional symptoms. Severe disease with isolated glomerulonephritis and pulmonary-renal syndrome occurs. Patients with signs and symptoms of AAV should be questioned regarding illicit drug use, particularly when dual MPO-ANCA and PR3-ANCA serology is present, and urine toxicology screen for the presence of cocaine and levamisole should be obtained.

The commonest prescription drug offenders include hydralazine and propylthiouracil (PTU), although penicillamine, minocycline, sulfasalazine, allopurinol, carbimazole, methimazole, and gold have all been implicated [75, 76]. Unlike levamisole-induced disease, the presentation of other drug-induced forms of disease mirrors idiopathic disease, with rapidly progressive glomerulonephritis being especially common. Serologically, patients generally have MPO antibodies at high titers, and dual positivity to MPO and PR3 is rare. Affected patients tend to be positive for other autoantibodies, including antinuclear antibody (ANA), anti-double-stranded DNA (anti-dsDNA), anti-histone, anti-lactoferrin antibodies, and other forms of ANCA, specifically anti-human neutrophil elastase (HNE). Propylthiouracil typically causes a pauci-immune necrotizing and crescentic glomerulonephritis, but other organ systems may be involved. While patients with PTU-induced disease tend to have high titers of MPO-ANCA, the ANA is not usually positive. In both illicit and prescription drug-induced AAV, cessation of the causative agent is imperative, and management is similar to that of the idiopathic forms of disease, employing immunosuppressive medication, as well as plasmapheresis and hemodialysis as indicated by disease severity.

Genetic Associations

The ability to sequence DNA from humans is becoming more and more facile, and investigators have taken full advantage of this to understand the genetic underpinnings of AAV, uncovering disease associations with both MHC and non-MHC genes [24]. Genome-wide association studies (GWAS) of patients and healthy controls of European descent revealed an association of PR3-ANCA positive AAV with *HLA-DP*, *SERPINA1* (encoding α -1 antitrypsin), and *PRTN3* (encoding PR3), whereas MPO-ANCA positive disease was associated with *HLA-DQ* [77, 78]. The largest risk was seen with single-nucleotide polymorphism (SNP) variants rs141530233 and rs1042169 at the *HLA-DPB1* locus [78]. Among non-MHC genes, an association were demonstrated with *CTLA4*, which encodes a T-cell surface molecule (CTLA-4) that down-regulates T-cell activation [77]. Two *CTLA4* single nucleotide polymorphisms (SNP), +49 G [51-53] and CT60 [77, 79, 80], have been implicated in several studies. All of the studies identifying disease association with the *CTLA4* SNP were performed in European cohorts comprising only Caucasian patients. No such association with *CTLA4* was found in Japanese patients with AAV [81]. The SNP

rs3087243 of the *CTLA4* gene [80], which encodes an inhibitory regulator of T-cell activation, and rs2476601 of the *PTPN22* gene [80, 82, 83], which encodes a regulator of cytoplasmic tyrosine kinase and T-cell function, are both associated with AAV in Caucasian European cohorts [80, 81, 83]. Mutations in these genes have been implicated in other autoimmune diseases, suggesting a predisposition to general immune dysregulation [80, 82].

Racial and geographic variability may reflect differences in genetic predisposition. AAV has been rarely described in Africa [8], and it is notably rare in African Americans. An association of the *HLA-DRB1*15* alleles with PR3-ANCA positive disease has been found, conferring a 73.3-fold higher risk in African American patients than in community-based controls [84]. These alleles were also associated with PR3-ANCA positive disease in Caucasians, but with an odds ratio of only 2.2. The *DRB1*1501* allelic variant, which is of Caucasian descent, was found in 50% of African American patients, whereas the *DRB1*1503*, of African descent, was under-represented in this group. Only the *DRB1*1501* allele was found in Caucasian patients. A significant association was found with *DRB1*16* in African American patients with MPO-ANCA positive disease. No allele has been so significantly associated with MPO-positive disease in Caucasians. In Chinese patients, the allelic variants *DRB1*1101* and *DRB1*1202* were observed significantly more often in patients with MPO-ANCA and PR3-ANCA-associated disease, respectively, than in healthy controls [85]. The finding in PR3-ANCA positive disease is difficult to interpret given the overall high prevalence of this allele in the Han population. This may reflect a particular AAV-associated haplotype. In Chinese Han population, variant rs3117242 of *HLA-DPB1* was found to be associated with GPA [86]. In a Japanese cohort, *HLA-DRB1*0901* was significantly associated with MPO-ANCA positive disease [81]. Collectively, these findings lend credence to the concept that MPO- and PR3-AAV are genetically distinct diseases with phenotypic overlap. This genetic difference between PR3- and MPO-AAV was also noted in a meta-analysis demonstrating stronger association by ANCA serotype than clinical phenotype [87].

CLINICAL PRESENTATION

The most commonly recognized presentation of AAV is pulmonary-renal syndrome, with alveolar hemorrhage and kidney injury that typically manifests as a rapidly progressive glomerulonephritis. However, presentation can be influenced to some extent by the type of disease be it GPA or MPA, as well as, duration of disease prior to presentation. In terms of kidney involvement, both GPA and MPA can present with severe kidney failure, at times requiring dialysis. EGPA less commonly involves the kidneys, and when it does, kidney disease tends to be less severe than in GPA or MPA. Dysmorphic hematuria with or without red blood cell casts, proteinuria, and an elevated creatinine are all clues to the diagnosis. Proteinuria is typically within the nephritic range (<3g/day), but nephrotic-range proteinuria does not exclude the diagnosis. Kidney disease can occur absent other clinical manifestations.

LABORATORY DIAGNOSIS

Any testing for AAV begins with clinical suspicion of disease. This typically prompts non-specific studies, such as blood tests and urine microscopy, to look for elevated creatinine and dysmorphic hematuria with or without red blood cell casts, respectively, as evidence of kidney involvement. Similarly, chest radiograph or computed tomography (CT) may be used to screen for pathological changes if present. In those with otolaryngologic symptoms, endoscopic examination with biopsy is preferred, followed by more specific avenues of investigation if necessary. Tissue biopsy is the gold standard for diagnosis of AAV. In the acute setting, the lesion common to all affected tissues is segmental inflammation with fibrinoid necrosis (Figure 1), often with accompanying neutrophil infiltration initially, followed in quick succession by mononuclear leukocyte infiltration [88, 89]. As disease progresses, the lesions become sclerotic. The finding of pauci-immune necrotizing crescentic glomerulonephritis strongly supports a diagnosis of AAV. However, lesions can be detected at various stages of development, so mild segmental fibrinoid necrosis with or without an adjacent crescent is common (Figure 1). If the acute lesion is severe, the glomerular tuft may have global necrosis with a circumferential crescent. In patients with granulomatous disease, GPA and EGPA, granulomatous inflammation most often affects the respiratory tract, including the lungs, rather than the kidneys, and is present concomitantly with small-vessel vasculitis. Lesions appear histologically as necrotic zones with surrounding mixed cellular infiltrate of neutrophils, lymphocytes, monocytes, macrophages, and often multinucleated giant cells. Eosinophils may also be present, but are more obvious, although not pathognomonic, in EGPA.

Anti-neutrophil cytoplasmic autoantibodies, first described by Davies and colleagues [90], have become routine in the diagnostic armamentarium of AAV. Treatment should not be delayed while awaiting results. A serologically-negative form of AAV is recognized in which current clinical assays do not detect MPO-ANCA or PR3-ANCA. By using highly sensitive epitope excision with mass spectrometry, Roth and coworkers identified a single small linear MPO epitope with high pathogenicity that was undetectable by usual assays due to obfuscation in serum by ceruloplasmin, the endogenous inhibitor of myeloperoxidase activity [91].

Figure 1. Photomicrographs of a kidney biopsy specimen from a patient with MPA showing a glomerulus (left panel) with segmental fibrinoid necrosis (F) and a cellular crescent (C), and an interlobular artery (right panel) with segmental fibrinoid necrosis (F). (Masson trichrome stain, X400).

Patients presenting with clinical signs and symptoms consistent with disease, but who are serologically negative, may have this or another as yet unidentified epitope that is not readily detected by currently available means. There are ANCA that occur in healthy individuals in very low titer that are not detected by routine serologic assays [92]. These are considered natural autoantibodies. Thus, while ANCA can be used to rule in disease in the appropriate clinical setting, neither their presence nor absence alone can be used to determine if disease is present. Additionally, some patients have persistently elevated autoantibody titers even in the absence of any clinical evidence of disease, thereby limiting their utility in diagnosing disease flares [93].

MANAGEMENT

Treatment of AAV can be considered in three phases: remission induction, remission maintenance, and treatment of relapse. Over the past decade, there has been an explosion of investigation into identifying ideal induction and maintenance strategies for patients with AAV.

Cyclophosphamide with corticosteroids has been used historically as induction therapy for AAV. Cyclophosphamide, an oxazaphosphorine that is chemically related to the nitrogen mustard family of alkylating agents [94], is the mainstay of AAV treatment. Multiple animal models have demonstrated its immunosuppressant activity apart from its antimetabolic or cytotoxic characteristic [95, 96].

Although there is no randomized trial studying the optimum dose with glucocorticoids, the question of oral versus pulse intravenous (IV) cyclophosphamide to reduce the cumulative exposure to cyclophosphamide has been looked at. The CYCLOPS trial compared pulse iv versus daily oral cyclophosphamide in 149 patients with AAV and found no difference in time to remission, but a lower rate of leukopenia in the pulse group (HR 0.41, CI 0.23-0.71) [97]. Though the relapse rate was higher in the IV group in a long term follow up study, the mortality and renal function was similar [98]. The cumulative dose of cyclophosphamide should be kept in mind when choosing a regimen.

More recently, great strides have been made using rituximab-induced B-cell depletion for induction of remission. Rituximab, a chimeric murine/human monoclonal antibody that depletes B-cells by binding CD20 and inducing antibody-dependent cellular cytotoxicity (ADCC), was reported to be non-inferior to cyclophosphamide for induction therapy in GPA and MPA in short- [99, 100] and long-term [101] follow-up. Rituximab is approved by the Food and Drug Administration and European Medicines Agency for induction therapy in patients with GPA and MPA.

Plasmapheresis has been used in AAV patients with diffuse alveolar hemorrhage and severe renal disease [102, 103]. The MEPEx trial randomized 137 patients with AAV and serum creatinine > 5.8 mg/dL to receive plasma exchange or intravenous prednisolone, in addition to cyclophosphamide and oral prednisolone. Plasma exchange reduced risk of end stage kidney disease at 3 and 12 months [103]. A randomized controlled trial (PEXIVAS) of plasma exchange and glucocorticoid dosing was conducted in 704 AAV by Walsh and colleagues, the preliminary unpublished results of which were presented at the 2018 meeting of the European Renal Association – European Dialysis and Transplant Association (ERA-

EDTA) suggesting that plasma exchange was not beneficial in preventing death or progression to ESRD.

B-cell depletion to durably maintain remission is a logical next step, and there are numerous case reports, case series, and retrospective studies that suggest efficacy of this strategy [104-106]. The Maintenance of Remission using Rituximab in Systemic ANCA-associated Vasculitis trial (MAINRITSAN), compared low dose rituximab with azathioprine for remission maintenance in 115 AAV patients. Although rituximab was superior to azathioprine in preventing relapse, azathioprine was tapered and stopped earlier, which limits the results of the study [107]. Currently, the RITAZAREM trial (NCT01697267) in the United States is underway to also address this question of remission maintenance.

Complete depletion of peripheral B-cells cannot continue indefinitely if toxicities associated with immunosuppression are to be avoided. Targeted depletion of only B-cells with the future capacity to produce pathogenic ANCA would be ideal. To this end, there are data suggesting that patients with active disease have a lower percentage of CD5+ B-cells compared to patients in remission, and that rituximab-exposed patients who have a robust reconstitution of CD5+ B-cells after therapy require less immunosuppression [108].

Novel treatment strategies aimed at other components of the inflammatory process, such as alternative complement pathway activation, are also needed. Alternative complement activation pathway products in kidney tissue (Bb) and urine (Bb, C3a, C5a, and soluble C5b-9) of patients with active disease correlate with severity of kidney injury [109]. In the mouse model of MPO-ANCA glomerulonephritis, blockade of the C5a receptor (C5aR) using an oral antagonist ameliorates disease in mice expressing human C5aR [110]. At present, a randomized phase 3 clinical trial (ADVOCATE) is underway to evaluate the safety and efficacy of C5aR blockade to induce remission in patients with ANCA vasculitis treated concomitantly with rituximab or cyclophosphamide/azathioprine (NCT02994927).

Mepolizumab is an anti-interleukin-5 monoclonal antibody that reduces eosinophilic inflammation, and has been successfully used to prevent exacerbations of eosinophilic asthma [111]. In a study of 136 relapsing or refractory EGPA, patients were treated with mepolizumab versus placebo [112]. Mepolizumab treatment was associated with a higher rate of remission (OR 16.74, CI 3.61-77.56) at 36 and 48 weeks. The Food and Drug Administration recently approved Mepolizumab for the treatment of EGPA in 2017.

There are several alternative drug options for maintenance immunosuppression, including azathioprine, mycophenolate mofetil, methotrexate, and leflunomide. Controlled trials of these various options are limited. A meta-analysis looking at the comparative efficacy of azathioprine, mycophenolate mofetil, methotrexate, and leflunomide found a 55% probability that leflunomide is superior to the other three agents for remission maintenance [113]. However, true head-to-head comparisons are lacking. Therefore, provider preference, patient tolerance, cost, and risk of drug-specific adverse effects all play a role in which medication is selected.

OUTCOMES

Although AAV is associated with high mortality, the introduction of immunosuppressive medications has improved the survival over time [114]. The objective now is to prevent relapse and preserve organ function.

The presence of kidney disease and its severity at presentation have long been recognized as important prognostic indicators of renal outcomes in patients with ANCA-associated vasculitis [115, 116]. A recent study investigating predictors of patient and renal survival in a Dutch cohort of 273 consecutive patients with ANCA vasculitis followed for almost twenty years [117] found that overall survival was better in patients without kidney involvement (hazard ratio [HR] 0.55, CI 0.33-0.92, $P = 0.02$). Renal survival was worse in MPO-ANCA positive patients (HR 2.1, CI 1.11-3.8, $P = 0.01$).

A study of 350 patients with AAV evaluated predictors of treatment resistance and relapse [118]. Altogether, 88% of those enrolled had kidney involvement at or near the time of diagnosis and followed longitudinally for a median of 49 months. Female or black patients and those with severe kidney disease appeared to be more resistant to initial therapy. Increased relapse risk was associated with the presence of lung (HR 1.71, CI 1.04-2.81) or upper airway disease (HR 1.73, CI 1.04-2.88) and PR3-ANCA positivity (HR 1.87, CI 1.11-3.14). Most importantly, however, severity of histopathologic findings at diagnosis does not predict patients for whom treatment would be futile [119]. While the presence of kidney disease is associated with poor renal outcomes [115, 116], lack of renal involvement is associated with increased risk of relapse [114]. More recently, a high neutrophil to lymphocyte ratio ($NLR > 5.9$) has been shown to predict more frequent relapse in AAV during follow-up [120].

Another controversy is routine monitoring of serum autoantibodies to predict relapses. Presence of PR3-ANCA at the time of remission maintenance has been associated with high rates of relapse [121]. In a recent study of 181 MPO-ANCA positive Japanese patients, the reappearance of MPO-ANCA, after negative conversion, was associated with relapse (OR 26.2, CI 8.2-101) [122]. However, 12-29% patients do not relapse despite reappearance of MPO-ANCA [93, 122, 123]. Thus, serial monitoring of ANCA may predict relapse, but given the high proportion of patients that do not relapse, it should not be used to guide therapy.

CONCLUSION

Upon hearing the first case reports of patients with GPA [55], Ludwig Aschoff, a renowned German pathologist, described the disease as “a new and very special disease” [124]. Over the past three decades, tremendous progress, more than could have been imagined as recently as the late 20th century, has been made through investigative efforts to understand the etiologies, pathogenesis and clinical management of AAV and glomerulonephritis. They have been transformed from diseases that were usually fatal to diseases that are chronic and manageable, with the potential for long-term, symptom-free remission. Nevertheless, many challenges remain. Ideally, investigations will focus on increasing the understanding of molecular mechanisms of genetic and environmental risk factors for disease, decreasing diagnostic delays to lessen the impact of disease on patient’s health, and further defining and personalizing treatment strategies that will induce and maintain remission while minimizing occurrence of relapse. Future pursuits, built upon the foundation of discoveries to date, may well lead to a cure.

Chapter 208

ANTI-GLOMERULAR BASEMENT MEMBRANE DISEASE

Stephen P. McAdoo*, PhD and Charles D. Pusey, MD

Centre for Inflammatory Disease, Department of Medicine,
Imperial College London, London, UK

ABSTRACT

Anti-glomerular basement membrane (anti-GBM) disease is a rare small vessel vasculitis that typically presents with rapidly progressive glomerulonephritis, often in combination with diffuse alveolar haemorrhage. It is characterised by the presence of directly pathogenic autoantibodies directed against antigens expressed in type IV collagen in glomerular and alveolar basement membranes. Treatment aims to rapidly remove these antibodies, and to suppress ongoing antibody production, with a combination of plasmapheresis, cyclophosphamide and prednisolone. When started promptly, the majority of patients respond successfully to treatment, though recovery from severe renal dysfunction presenting with a requirement for dialysis is uncommon. In contrast to other forms of glomerulonephritis and vasculitis, relapse in anti-GBM disease is exceedingly rare, as is recurrent disease after renal transplantation. Despite its rarity, anti-GBM has been extensively studied and now serves as model autoimmune disorder, with recent studies describing novel mechanisms of HLA-associated immune susceptibility, epidemiologic clustering of disease suggesting the importance of environmental exposures, and a potential role for injurious T cell responses in inciting disease

Keywords: ANCA-associated vasculitis, basement membrane, antibodies

INTRODUCTION

Anti-glomerular basement membrane (GBM) disease is a rare small vessel vasculitis that usually presents with rapidly progressive glomerulonephritis, diffuse alveolar hemorrhage, or both. It is typified by the presence of autoantibodies directed against antigens intrinsic to the glomerular and alveolar basement membranes, which can be detected in serum or deposited in tissue, and it is therefore classified an immune-complex small vessel vasculitis in the Revised International Chapel Hill Consensus Conference Nomenclature of Vasculitides [1]. The Consensus acknowledges the relative misnomer of anti-*glomerular* basement membrane disease, given the frequent involvement of alveolar basement membranes, though recognizes the widely accepted use of anti-GBM disease to describe this condition regardless of lung involvement. The Consensus also recognizes the phasing out of eponymous terminology in the classification of vasculitides, though the term ‘Goodpasture Disease’ is still often used to describe this condition, a reference dating back to a case of necrotizing glomerulonephritis and lung hemorrhage in 1919, that was at the time attributed to atypical influenza infection [2]. It was not until the 1970s, however, and the explosion in immunological laboratory methods, that the disease was fully described [3], following the demonstration of deposited anti-GBM antibodies in renal tissue [4], their detection in circulation [5], and ultimately their pathogenic potential upon passive transfer to non-human primates [6]. Treatment with plasmapheresis and immunosuppression, to rapidly remove these pathogenic autoantibodies and to prevent their ongoing production, was introduced a few years later [7], and remains the mainstay of current treatment approaches, though novel agents are under investigation. Despite its rarity, anti-GBM disease has served as a model for the study of autoimmunity, and it is often regarded as a prototypic antibody-mediated disease. However, the recent recognition of a role for cellular immune effectors in experimental models, studies of the molecular basis of genetic susceptibility to disease, and the description of atypical clinical presentations, highlight that the immuno-pathogenic mechanisms underlying anti-GBM are not yet fully understood, and require further investigation to improve treatment strategies and clinical outcomes.

EPIDEMIOLOGY

Anti-GBM disease is rare, with an estimated incidence of 1-2 per million population (pmp)/year (yr) in European populations, based on single-center biopsy- or serology-based series. A recent study from Ireland was the first to define a nationwide disease incidence, by identifying all cases over a decade via reference immunology laboratories and a national pathology database, reporting a rate of 1.64 pmp/yr [8]. The disease is well recognized in Asian populations [9-12], though is thought to be rarer in African populations [13].

Single-center series suggest that 15-20% of pulmonary-renal syndromes are caused by anti-GBM disease [14-16], and large renal biopsy series show that it accounts for 10-15% of all cases of crescentic glomerulonephritis [17], though it appears to be a rare cause of end-stage renal disease (ESRD) in both adults and children [18, 19]. Anti-GBM disease has a bimodal age distribution, with a peak incidences in the 3rd decade, where a slight male

preponderance and presentation with both kidney and lung disease are observed, and in the 6-7th decades, where presentation with isolated kidney disease is more common [20-22].

GENETIC ASSOCIATIONS

The precise etiology of anti-GBM disease remains obscure, though it is likely that environmental triggers act in genetically susceptible individuals to induce disease onset. Anti-GBM disease has strong HLA-gene associations, with approximately 80% of patients inheriting an HLA-DR2 haplotype [23]. A hierarchy of associations with particular *DRB1* alleles has been identified, some positively associated with disease, such as *DRB1*1501*, an observation that has been replicated in both Caucasian and Asian populations [23-25], and some conferring a dominant-negative protective effect (e.g., *DRB1*01*). It has previously been suggested that the dominant-negative effect might be attributed to the higher affinity of the latter allele for binding peptides from the target autoantigen (thus preventing their favorable presentation on MHC molecules) [23], though a recent series of studies using mice transgenic for human HLA molecules (and lacking murine MHC Class II) suggest novel mechanisms of HLA-disease association. These experiments confirmed epidemiologic observations in humans: *HLA-DR15* transgenic mice are susceptible to the induction of experimental anti-GBM disease, whereas mice expressing either *HLA-DR1* or both *HLA-DR15* and *-DR1* are resistant [26, 27]. These studies suggest that presentation of the immunodominant T-cell epitope in the distinct binding registries of *HLA-DR15* and *-DR1* can differentially induce conventional and tolerogenic T cell responses, respectively, thus accounting for the dominant protective effect of *HLA-DR1* via induction of antigen-specific regulatory T cells, even when co-inherited with the *HLA-DR15* susceptibility allele.

In contrast to other antibody, associated glomerular diseases, such as anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis and membranous nephropathy, where genome-wide association studies have identified polymorphisms in the target autoantigen associated with disease susceptibility, a small study did not identify any polymorphisms in *COL4A3*, the gene encoding the anti-GBM disease autoantigen, related to disease predisposition [28]. This observation may require validation in a larger cohort of patients, however, before polymorphisms in *COL4A3*, or other collagen genes, can be definitively excluded from playing a role in disease pathogenesis.

ENVIRONMENTAL ASSOCIATIONS

Goodpasture's original description of pulmonary-renal syndrome occurred during an influenza outbreak in 1919, and other small series of anti-GBM disease have likewise been described in association with influenza infection [29, 30]. Other reports have described seasonal variation and 'outbreaks' of anti-GBM disease [20, 21], and a recent Chinese study identified a high proportion of patients with prodromal respiratory tract infection at the time of anti-GBM disease diagnosis [31]. These observations suggest that those environmental triggers such as infection may contribute to disease onset, a hypothesis that is further supported by the formal identification of both spatial and temporal clustering of cases in the

recent Irish study [8]. A number of mechanisms may account for this association with infection – studies in experimental animal models, for example, suggest auto-reactivity to basement membrane antigens may arise through a process of ‘molecular mimicry’ or idiotype anti-idiotype interactions following a primary response to microbial or other foreign peptides [32, 33]. Of note, excess reactivity to microbial peptides has been described in patients with anti-GBM disease [34]. It is also possible that usually quiescent autoreactive lymphocytes undergo ‘bystander activation’ because of systemic inflammatory responses, or that pulmonary inflammation at times of infection may release usually sequestered alveolar basement membrane antigens to immune detection.

The release of sequestered antigens may also account for the association of pulmonary irritant exposure and the development of lung hemorrhage in anti-GBM disease, which occurs in nearly all patients who smoke but less frequently in non-smokers [35]. Hydrocarbon exposure has likewise been implicated in disease onset [36, 37], and there are case reports of anti-GBM disease after use of inhaled recreational drugs including cocaine and amphetamine [38-40]. It has been suggested that pulmonary irritants may increase capillary permeability, thus predisposing to alveolar bleeding, or that they may modify or expose sequestered basement membrane antigens to immune detection, resulting in disease enhancement.

IMMUNOPATHOGENESIS

The Autoantigen

The collagen IV family consists of six genetically distinct α -chains ($\alpha 1$ -6) that trimerize with each other to make specific triple-helical protomers: $\alpha 1\alpha 1\alpha 2$, $\alpha 3\alpha 4\alpha 5$, and $\alpha 5\alpha 5\alpha 6$. The expression of the $\alpha 3\alpha 4\alpha 5$ protomer is almost exclusively restricted to the glomerular and alveolar basement membranes (with the $\alpha 1\alpha 1\alpha 2$ protomer being most abundantly expressed elsewhere), and the clinical pattern of renal-pulmonary disease thus reflects the restricted expression of this antigen to these locations. In the GBM, these $\alpha 3\alpha 4\alpha 5$ protomers polymerize end-to-end via their C-terminal non-collagenous domains (NC1) to form hexameric NC1 structures. Specialized sulfilimine bonds cross-linking opposing trimeric NC1 domains reinforce the quaternary structure of this hexamer. It has recently been shown that the generation of these crosslinks, between methionine and lysine residues in the non-collagenous domains, is dependent on the activity of peroxidasin, a peroxidase enzyme that generates hydrobromous acid, a critical intermediate for crosslink formation [41, 42]. The $\alpha 3\alpha 4\alpha 5$ protomers likewise associate via their N-terminal 7S domains to complete a lattice-like network that is essential for glomerular structure and function. The primary target of the autoimmune response in anti-GBM disease was first identified as a 27kDa protein in collagenase-solubilized GBM preparations, and subsequently shown to be the non-collagenase domain of the $\alpha 3$ chain: $\alpha 3(\text{IV})\text{NC1}$ [43, 44]. Immunization with either collagenase-solubilized or recombinant forms of this protein from various species induces disease in a number of animal models, confirming the universal antigenicity of this protein.

HUMORAL IMMUNITY

Anti-GBM disease is regarded as a prototypic antibody-mediated condition, following the seminal observation of disease induction following passive transfer of autoantibody from humans to Squirrel monkeys [6]. All patients with typical anti-GBM disease have antibodies reactive to $\alpha 3(\text{IV})\text{NC1}$, and a proportion also demonstrate reactivity to $\alpha 4$ or $\alpha 5$ chains, identified either in serum or upon elution from kidney tissue, which may arise secondarily due to a process of ‘epitope-spreading’ within the collagen IV network [45]. Studies in animal models suggest that anti- $\alpha 5$ antibodies also have direct pathogenic potential, and their detection is associated with worse prognosis, though reports of human disease in the native kidney caused by anti- $\alpha 5(\text{IV})\text{NC1}$ antibodies (without concurrent anti- $\alpha 3(\text{IV})\text{NC1}$ antibodies) are exceptionally rare [46].

Two key B-cell epitopes within $\alpha 3(\text{IV})\text{NC1}$ are recognized, designated E_A (incorporating residues 17–31 toward the amino terminus) and E_B (residues 127–141 toward the carboxy terminus) [47]. In disease, antibodies tend to be of the IgG1 and IgG3 subclass, and their titer and avidity have been associated with disease severity [48–51]. Once bound in the kidney, these antibodies can initiate a local inflammatory response *via* both complement- and FcR-dependent mechanisms. It is notable, however, that low-level natural autoantibodies that recognize the same epitopes can be identified in healthy individuals, though they tend to be of different subclass (Ig2 and IgG4 dominant) [52]. In addition, the presence of circulating anti-GBM antibodies can predate the onset of clinical disease by several months [53]. These observations suggest that additional factors contribute to disease pathogenesis.

CELLULAR IMMUNITY

The strong HLA association, the detection of high-affinity, class-switched autoantibody, and the phenomenon of ‘epitope spreading,’ indicates a requirement for T cell help in the generation of anti-GBM antibodies. Indeed, peripheral CD4⁺ cells from patients have been shown to proliferate in response to $\alpha 3(\text{IV})\text{NC1}$ (as do cells from healthy individuals, but at much lower frequency), and the frequency of autoreactive CD4⁺ T cells has been shown to correlate with disease activity [54, 55].

Studies in experimental models of anti-GBM disease also suggest that directly nephrogenic T-cell responses may contribute to disease pathogenesis. In early avian models, mononuclear cells could transfer disease to bursectomised birds [56], and B cell deficient mice develop glomerular injury following immunization with $\alpha 3(\text{IV})\text{NC1}$ [57]. Disease has also been transferred by CD4⁺ T-cells from nephritic rats, expanded *in vitro* by stimulation with $\alpha 3(\text{IV})\text{NC1}$, without detectable antibody responses, suggesting directly injurious responses by cellular effectors [58]. In a series of experiments using HLA transgenic mice, Ooi et al identified an immunodominant T-cell epitope within $\alpha 3(\text{IV})\text{NC1}$ that can induce both autoantibody production and glomerulonephritis in mice expressing the human *DRB1*1501* susceptibility allele (but not in mice expressing the protective *DRB1*01* allele) [26]. In addition, CD4⁺ T-cell clones generated from *DRB1*1501* transgenic mice and specific for the immunodominant T-cell epitope transferred disease to naïve animals. In a rat model, immunization with an immunodominant T-cell epitope resulted in glomerular injury,

followed by the expansion of B cell responses to distinct $\alpha 3(\text{IV})\text{NC1}$ epitopes in renal draining lymph nodes [59]. It has thus been suggested that T-cell mediated glomerular injury may be the inciting event in anti-GBM disease, that then triggers *de novo* 'internal' immunization to B-cell epitopes released from damaged GBM, and subsequent autoantibody production required for full expression of disease. Direct evidence of this phenomenon in humans is lacking, though historical case reports of patients who developed glomerulonephritis prior to the deposition of anti-GBM antibodies, and the detection of an early T-cell infiltrate in pathology studies [60, 61], suggests that cell-mediated injury may occur in at least a subset of patients.

TOLERANCE AND AUTOIMMUNITY

$\alpha 3(\text{IV})\text{NC1}$ is expressed in human thymus [55, 62], though the finding of natural autoantibodies and autoreactive T cells in healthy individuals suggests central tolerance to the antigen is incomplete. However, additional immune 'check-points' must be broken for disease to develop. Of note, the B cell epitopes within native $\alpha 3(\text{IV})\text{NC1}$ are cryptic, being sequestered within the quaternary structure of the hexameric NC1 structure stabilized by sulfilamine cross-links, such that they remain protected from immune surveillance in normal circumstances [63]. It has been shown that patient-derived anti-GBM antibodies do not bind cross-linked $\alpha 3\alpha 4\alpha 5$ hexamers until they are dissociated, and it is proposed that the resistance of some mouse strains to experimental anti-GBM disease is due to extensive cross-linking in murine GBM [64]. Thus a process of 'conformational transformation' of the cross-linked $\alpha 3\alpha 4\alpha 5$ hexamer is thought to be critical to disease pathogenesis, by exposing hidden epitopes to immune detection, and allowing the binding of pathogenic autoantibodies [45]. This may explain the association of anti-GBM disease with other pathologies that physically disrupt or modify the structure of the glomerular (e.g., ANCA vasculitis, lithotripsy) or alveolar (e.g., smoking) basement membranes, and of the induction of humoral responses following T cell mediated glomerular injury.

Relapses are rare in anti-GBM disease, suggesting that immune tolerance can be reinstated as disease resolves. This is supported by the finding of an expanding population of CD25+ antigen-specific T cells in patients after their acute presentation, that may suppress responses to $\alpha 3(\text{IV})\text{NC1}$ [65].

CLINICAL PRESENTATION AND DIAGNOSIS

The majority of patients present with rapidly progressive glomerulonephritis (RPGN). As such, a short prodrome of non-specific constitutional symptoms is typical, culminating with overt features of oliguria, fluid overload and uremia. Approximately half of patients require hemodialysis at the point of initial presentation [22]. Loin pain, attributable to distension of the renal capsule, and visible hematuria are recognized. Urine microscopy may identify dysmorphic erythrocytes or red blood cells casts. Proteinuria is usually in the sub-nephrotic range ($<3\text{g/day}$), perhaps reflecting a severe reduction in glomerular blood flow that limits the rate at which protein filtration can occur.

Approximately 40-60% of patients have concurrent alveolar hemorrhage, which is more common in young male patients, and in current smokers [35]. It may present with cough, dyspnea, and hemoptysis, or be apparent radiographically. A disproportionately severe iron-deficient anemia should also alert to the possibility of covert underlying alveolar bleeding. A small proportion of patients (<10%) may present with isolated pulmonary disease in the absence of renal involvement. In one small series, it was found that 11% of patients with lung hemorrhage required artificial ventilation during their treatment for anti-GBM disease [66].

The presence of extra-renal/pulmonary manifestations is uncommon in anti-GBM disease, and may suggest an alternative cause of pulmonary-renal syndrome, or that the patient has co-existing ANCA positivity.

Central to the diagnosis of anti-GBM disease either is the identification of anti-GBM antibodies, in serum or deposited in tissue, along with pathological features of crescentic glomerulonephritis, with or without evidence of alveolar hemorrhage.

SEROLOGIC TESTING

Circulating anti-GBM antibodies were first described using indirect immunofluorescence techniques on normal human or primate kidney [5]. In current practice, a variety of commercial immunoassays is available, which are accepted to have high sensitivity and specificity [67]. These may use native human or animal GBM isolates, or more commonly recombinant $\alpha 3(\text{IV})\text{NC1}$ preparations. It is recognized that between 5-10% of patients with demonstrable anti-GBM antibody on renal biopsy are negative by conventional serum assays. As summarized in a recent commentary by Glasscock [68], this may be due to:

- Intrinsic sensitivity of the chosen assay
- Isotope or subclass of antibody not being detectable (e.g., for example, rare cases of IgA or IgG4 mediated anti-GBM disease are described)
- Antibody disappearance prior to clinical resolution
- The ‘immunological sink’ – high affinity antibodies rapidly bind tissue and are removed from circulation, with only low affinity antibodies remaining,
- Absence of relevant epitopes in antigens used in the detection assay
- T-lymphocyte, complement or other mediators causing tissue damage rather than a predominantly antibody mediated process

A proportion of patients who have demonstrable deposition of IgG on the GBM by immunofluorescence, but who are negative for circulating antibodies by these conventional techniques, may be positive when tested by highly sensitive biosensor assay [69]. These cases demonstrate that serological tests, though useful for rapid diagnoses, should not be the sole means of excluding a diagnosis of anti-GBM disease, and reinforces the importance of performing a renal biopsy when possible.

DEPOSITED ANTIBODY

Direct immunofluorescence for immunoglobulin on frozen kidney tissue has high sensitivity for detecting deposited antibodies, and is the gold standard for diagnosis of anti-GBM disease, typically showing a strong linear ribbon-like appearance (Figure 1A). Other causes of linear fluorescence should be excluded (including diabetes, monoclonal paraproteinemia, lupus nephritis, and rarely fibrillary glomerulonephritis). In addition, it should be noted that fluorescence might be negative or unclear in cases with severe glomerular inflammation, where the underlying architecture is so disrupted that the linear pattern may not be recognized. In typical anti-GBM disease, these deposits are polyclonal and do not show light-chain restriction. Immunoperoxidase techniques using paraffin-embedded tissue may also be used, but may be less sensitive. In our experience, immunofluorescence on lung tissue is rarely informative.

Conventional direct immunofluorescence techniques will identify all IgG subclasses, though will not differentiate the antigenic target of the kidney-bound antibody, and so may detect anti- $\alpha 3$ (IV) NC1, anti- $\alpha 5$ (IV)NC1, or other antibodies recognizing GBM components. Antibodies to non-collagen chain antigens, such as nidogen (entactin), have been identified in historical case series [70, 71], though their significance is not well characterized. In addition to detecting deposited anti-GBM antibody, immunofluorescence may demonstrate the presence of complement components, in particular C3 and C1q, along the GBM [21]. A proportion of patients may also demonstrate immunoglobulin or complement deposition along tubular basement membranes.

RENAL BIOPSY FINDINGS

Almost all patients with anti-GBM disease will have evidence of crescent formation on kidney biopsy (Figure 1B), and in 80% of patients more than 50% of glomeruli will be affected. The average proportion of affected glomeruli is approximately 75% [17, 72]. The proportion of crescents observed in the biopsy correlates strongly with the degree of renal impairment at presentation [21, 22]. These crescents will typically be of uniform age (Figure 1C), in contrast to other causes of RPGN, where a mixture of cellular, fibrocellular and fibrous crescents may be seen. Asynchronous crescent formation, or the presence of necrotizing vasculitis in larger blood vessels on renal biopsy, should thus alert to the possibility of a concomitant ANCA-mediated process. Given the acuity of disease onset, interstitial fibrosis and tubular atrophy are uncommon in anti-GBM disease (unless there is pre-existing kidney pathology) though interstitial inflammation may be observed. Electron-dense deposits are not seen in isolated anti-GBM disease, though electron microscopy is necessary to exclude concomitant glomerular pathologies, such as membranous glomerulonephritis, and may identify other diseases that may cause linear fluorescence (such as fibrillary GN and diabetic GBM thickening).

DIAGNOSIS OF ALVEOLAR HEMORRHAGE

There are no uniform diagnostic criteria for the diagnosis of diffuse alveolar hemorrhage, and diagnosis is often made on a combination of clinical, radiological and laboratory findings. This may account for the variable frequency of lung hemorrhage described in clinical series of anti-GBM disease.

Plain chest radiography may demonstrate non-specific diffuse opacification patterns with occasional predilection for the midzones and apical and costophrenic sparing [73]. High-resolution computed tomography may show ground-glass opacifications due to alveolar filling with blood, which may progress to frank consolidation, again with peripheral sparing. As hemorrhage is resorbed in the pulmonary interstitium, later imaging may show reticular or nodular appearances [74].

Figure 1. Renal biopsy findings in anti-GBM disease. (A) Immunofluorescence for IgG in anti-GBM disease, showing bright linear deposits along glomerular (and to a lesser extent, tubular) basement membranes. (B) Hematoxylin and eosin staining in anti-GBM disease, showing a circumscribed glomerular crescent with compression of the underlying tuft. Red blood cells casts are present in tubular lumens. (C) Jones methenamine staining in anti-GBM disease, clearing delineating glomerular basement membranes, large circumferential and synchronous crescent formation in adjacent glomeruli, with associated rupture of Bowman's capsule.

Acute alveolar hemorrhage may be indicated by the finding of hemorrhagic broncho-alveolar lavage fluid, classically with increasing blood content on successive washes. After 2-3 days, alveolar macrophages convert hemoglobin to hemosiderin, and these hemosiderin-laden cells may persist in the lung for several weeks, being evident on Perls staining of broncho-alveolar samples [75]. Threshold proportions of 20-30% hemosiderin-laden cells of the total macrophage count have been suggested to be strongly indicative of diffuse alveolar hemorrhage.

An increase in diffusing capacity of the lung for carbon monoxide (KCO) has been reported in alveolar hemorrhage in anti-GBM disease, being attributed to increased CO uptake by intra-alveolar erythrocytes [76]. However, this finding may not be present in all cases [66], perhaps due to ventilation-perfusion mismatch in a proportion, such that measurement of KCO may have useful positive, but not negative, predictive value.

Lung biopsy is rarely performed in cases of alveolar hemorrhage in anti-GBM disease. When undertaken, it is likely to show alveolar lumens filled with erythrocytes and hemosiderin-laden cells. Pulmonary capillaritis may be present, with features of fibrinoid necrosis of capillary walls and inflammation and edema of the alveolar interstitium [77].

TREATMENT

The combination of immunosuppression and plasmapheresis to treat anti-GBM disease was first described in 1976 [7], and it remains the core recommendation of the latest KDIGO guideline for treating anti-GBM GN [78]. We have reproduced a recommended treatment schedule (Table 1).

Plasmapheresis aims to rapidly remove directly pathogenic anti-GBM antibodies from the circulation, and its use is supported by observational studies that suggest improved renal and patient survival compared to historical or contemporaneous cohorts treated with immunosuppression alone [22, 79, 80], and one small randomized trial [81]. The American Society for Apheresis (ASFA) includes anti-GBM disease in its recommendations for therapeutic plasmapheresis (Grade 1B, 1C) [82]. Immunoabsorption is an alternative form of extra-corporeal therapy that may be more efficient than plasma exchange for the removal of pathogenic autoantibody (though conversely it may not remove pro-inflammatory or pro-coagulant factors). In small series, it appears to have comparable outcomes to plasma exchange therapy [83, 84].

In addition to plasma exchange therapy, immunosuppression and corticosteroid treatment are required to prevent ongoing autoantibody production to reduce renal and pulmonary inflammation. Daily oral cyclophosphamide and oral prednisolone are the most commonly used agents, forming the basis of nearly all published experience in anti-GBM disease. An uncontrolled retrospective analysis suggests that daily oral cyclophosphamide may be superior to pulsed intravenous treatment [85], in contrast to AAV. The use of other immunosuppressive therapies is less well described [86-88]. Rituximab is an effective treatment for a number of other autoantibody associated glomerular diseases, though published experience in anti-GBM disease is limited to approximately 20 cases [89-98], where it has most commonly been used as adjunctive or second-line therapy in resistant disease. It appears to be associated with immunological response, though clinical outcomes

are variable. At present, there is insufficient evidence to recommend its use first-line in the treatment of anti-GBM disease; however, it may be considered where there are compelling contra-indications to cyclophosphamide therapy or as adjunctive treatment in severe disease. Rituximab may also be considered for expediting antibody clearance in patients awaiting renal transplantation who remain seropositive.

Table 1. Initial treatment of Anti-GBM disease (adapted from references [13, 140])

Agent	Details and Duration	Cautions
Plasma exchange	Daily 4 L exchange for 5% human albumin solution. Add fresh human plasma (300-600 mL) within 3 days of invasive procedure (e.g., kidney biopsy) or in patients with alveolar hemorrhage. Continue for 14 days or until antibody levels are fully suppressed. Monitor antibody levels regularly after cessation of treatment as plasma exchange may require reinstatement if antibody levels rebound.	Monitor and correct as required: platelet count; aim $>70 \times 10^9/L$; fibrinogen; aim >1 g/L (may require cryoprecipitate supplementation to support PEX); hemoglobin, aim for >90 g/L; corrected calcium, aim to keep in normal range
Cyclophosphamide	2 mg/kg/day given orally for 2–3 months. Reduce dose to 2 mg/kg in patients >55 years.	Stop if leukocyte count falls to $<4 \times 10^9/L$ and restart at reduced dose when recovered. Insufficient evidence to recommend use of IV cyclophosphamide.
Corticosteroids	Prednisolone 1 mg/kg/day (maximum 60 mg) given orally. Reduce dose weekly to 20mg by 6 weeks, then gradually taper until complete discontinuation at 6–9 mo.	There is no evidence to support the use of methylprednisolone, and it may increase the risk of infection
Prophylactic treatments	Prophylaxis against oropharyngeal fungal infection (e.g., nystatin, amphotericin, or fluconazole) while on high-dose steroids. Peptic ulcer prophylaxis (e.g., with PPI) while on high-dose steroid treatment. Prophylaxis against PCP (e.g., cotrimoxazole) while receiving high-dose corticosteroids and cyclophosphamide. Consider acyclovir for CMV prophylaxis. Consider prophylaxis against HBV reactivation (e.g., lamivudine) in patients who have evidence of previous infection (HBV cAb positive).	H ₂ receptor antagonists in those who are intolerant of PPI. Cotrimoxazole may contribute to leukopenia; monitor leukocyte count. Alternatives include nebulized pentamidine.

Abbreviations: cAb = core antibody; CMV = cytomegalovirus; GBM = glomerular basement membrane; HBV = hepatitis B virus; IV = intravenous; PCP = *Pneumocystis jiroveci* pneumonia; PEX = plasma exchange; PPI = proton pump inhibitor. Table adapted from reference [13].

Novel therapies undergoing evaluation in anti-GBM disease include IdeS (IgG-degrading enzyme of *S. pyogenes*), a streptococcal enzyme that is able to cleave both circulating and membrane-bound immunoglobulin [99]. IdeS was safe and tolerable in early phase human studies, and was shown to be effective for the removal of anti-HLA antibodies in patients undergoing renal transplantation [100]. A clinical study in severe anti-GBM disease, where it may promote rapid clearance of pathogenic autoantibody, is ongoing (EudraCT number: 2016-004082-39). We have recently shown that treatment with fostamatinib, a spleen tyrosine kinase (SYK) inhibitor, effectively reverses crescent formation in rodent models of anti-GBM disease [101, 102] (and that intra-glomerular SYK can be detected in patient kidney biopsies [103]) so it would be of interest to explore the use of this agent in advanced clinical disease.

OUTCOME AND PROGNOSIS

Diffuse alveolar hemorrhage secondary to anti-GBM disease appears to be highly responsive to treatment, with 90-100% of cases responding to immunosuppression and plasmapheresis [22, 66]. Data on long-term respiratory outcomes, however, are scarce. One small study suggested that patients who had lung hemorrhage have significantly reduced KCO compared to controls without lung involvement [104]. However, a subsequent larger series suggested that long-term respiratory sequela after lung hemorrhage in anti-GBM disease are not common [66]. This is in contrast to AAV, where interstitial lung disease is increasingly recognized as an important long-term complication, especially in patients positive for MPO-ANCA, suggesting that distinct mechanisms of pulmonary injury in these diseases [105, 106].

Renal outcomes in anti-GBM disease may be more variable. Long-term follow up of the largest cohort of patients ($n = 71$) all treated with the combination of plasma exchange, cyclophosphamide and corticosteroids, suggests that this approach is effective in preserving independent kidney function in the majority of patients, including those who present with severe kidney dysfunction, provided they do not require dialysis at presentation [22]. In patients presenting with creatinine values $<500\mu\text{mol/L}$, renal survival was 95% and 94% at 1- and 5- years respectively. In patients presenting with creatinine $>500\mu\text{mol/L}$, but not requiring immediate dialysis, renal survival was 82% and 50% at the same respective time-points. In patients presenting with an initial requirement for dialysis, however, renal recovery occurred in only 8% at 1 year. Other reports have described similarly low levels of renal recovery in patients presenting with dialysis-dependent kidney failure, with the highest rate of approximately 20% recovery in one series [107].

Predictors of poor renal outcome include severe renal dysfunction at diagnosis, the proportion of glomeruli affected by crescents, and oliguria at presentation [21, 22, 108]. A recent worldwide, multi-center study recruited 123 cases of renal biopsy-proven anti-GBM glomerulonephritis, making it the largest histopathological study in anti-GBM disease to date [109]. It confirmed previous observations of more favorable outcomes in patients presenting with creatinine of $<500\mu\text{mol/L}$. Independent predictors of ESRD were dialysis-requirement at presentation, reduced proportion of normal glomeruli, and increased interstitial infiltrate on kidney biopsy. Of note, no patient with 100% crescents or $>50\%$ sclerotic glomeruli recovered renal function, and so withholding treatment may be considered in these cases if lung hemorrhage is not present. Rare cases of renal recovery despite adverse pathologic findings [110, 111], however, highlights the need to consider all cases for treatment, with specific attention to other features that might predict renal recovery on biopsy (such as concomitant acute tubular injury). A short trial of early treatment may be considered, and rapidly tapered if there is no evidence of renal recovery within 2-4 weeks. In addition, the potential benefit of a period of immunosuppression to expedite autoantibody clearance, thus allowing earlier kidney transplantation, should be considered in suitable patients.

Relapse is rare in anti-GBM disease, occurring in fewer than 3% of patients [22]. It is usually associated with ongoing exposure to pulmonary irritants such as cigarette smoke or hydrocarbons [112, 113], and avoidance of these precipitants is an essential part of long-term management of these cases. We recommend repeat kidney biopsy in cases of relapse with kidney involvement, in order to secure an accurate diagnosis and to exclude concomitant

pathologies such as AAV and membranous nephropathy. In confirmed cases, standard re-treatment with cytotoxic medications and corticosteroids is usually indicated.

The long-term outcome of patients who progress to ESRD due to anti-GBM GN appears to be comparable to patients with ESRD of other causes, whether they remain on dialysis or undergo kidney transplantation [18, 114]. It should be noted, however, that kidney transplantation performed in the presence of anti-GBM antibodies results in a high likelihood of disease recurrence in the allograft, at frequencies of up to 50% in historical series [115], and that a period of at least six months sustained seronegativity is advised prior to undertaking transplantation in patients who have reached ESRD due to anti-GBM disease [78]. Under these circumstances, and with current immunosuppressive regimens, recurrent disease is rare [18].

VARIANT PRESENTATIONS OF ANTI-GBM DISEASE

Double-Positive Anti-GBM and ANCA-Associated GN

In some series, almost half of patients with anti-GBM disease have detectable ANCA (usually recognizing myeloperoxidase, MPO), and up to 10% of patients with ANCA have circulating anti-GBM antibodies [116-118]. This phenomenon was first reported within a few years of the first description of ANCA [116, 119], and while it is clear that the autoantibodies are antigenically distinct [120], the mechanism of this association is not understood. It has been shown that ANCA may be detected before the onset of anti-GBM disease, suggesting that ANCA-induced glomerular inflammation may be a trigger for the development of an anti-GBM response, perhaps by modifying or exposing usually sequestered disease epitopes in GBM [53].

These 'double-positive' patients appear to have a hybrid clinical phenotype, experiencing the early morbidity and mortality of anti-GBM disease, with severe kidney and lung disease at presentation, requiring aggressive immunosuppressive therapy and plasma exchange [121]. There is a suggestion they may be more responsive to treatment, with increased rates of recovery from dialysis. During long-term follow-up, however, they relapse at a frequency comparable to patients with AAV, suggesting they warrant more careful long-term follow up and maintenance immunosuppression, unlike patients with single-positive anti-GBM disease.

Anti-GBM Disease Associated with Membranous Nephropathy

There are several reports of anti-GBM disease associated with membranous nephropathy, occurring as a preceding, simultaneous, or succeeding diagnosis [122, 123]. As with the ANCA-association, it is postulated that disruption of glomerular architecture by one disease reveals hidden epitopes that allow the second process to occur. A rapid decline in kidney function in a patient with known membranous nephropathy should raise suspicion of the development of superimposed crescentic nephritis or anti-GBM disease, and re-biopsy is recommended. We suggest that such cases are treated initially as for anti-GBM disease, though how they should be managed in the long-term is not clear. The authors of a recent case

report suggest that rituximab may be a useful agent to treat both pathologies simultaneously [92].

Post-Transplant Anti-GBM Disease in Alport Syndrome

After kidney transplantation for Alport syndrome, recipients may develop anti-GBM antibodies as an alloimmune response to the neo-antigens contained in ‘normal’ $\alpha 3$, $\alpha 4$ or $\alpha 5$ chains expressed in the kidney allograft. In classical X-linked Alport syndrome (caused by mutations in the *COL4A5* gene encoding the $\alpha 5$ collagen chain) these antibodies do not recognize the individual E_A and E_B epitopes of the $\alpha 3$ chain recognized by sera from typical Goodpasture patients, but rather a distinct, composite epitope on the $\alpha 5$ chain, that is not sequestered within the native hexamer of the Goodpasture antigen [45]. It should be noted that commercially available anti-GBM assays, which are optimized to detect reactivity to the $\alpha 3(IV)NC1$ antigen, might fail to detect circulating antibodies in this setting. Anti-GBM antibodies may be detected in 5-10% of Alport patients following transplantation, though the development of overt glomerulonephritis in the allograft is less frequent (perhaps owing to the effects of maintenance immunosuppression). When glomerulonephritis develops, however, it usually occurs early and carries a high risk of graft loss [124, 125]. Repeated transplantation in this setting almost invariably leads to more aggressive disease recurrence and rapid graft loss, and is undertaken at very high risk [126]. Individuals with large *COL4A5* gene deletions are at increased risk of post-transplant anti-GBM disease, and recent guidelines encourage the use of genetic testing to inform discussions regarding the risk of *de novo* anti-GBM disease after transplantation [127].

‘ATYPICAL’ ANTI-GBM DISEASE

‘Atypical Anti-GBM disease’ is a term that has been used variably to describe cases with classical linear IgG staining on renal biopsy, but uncharacteristic clinicopathologic features. A large series ($n = 20$) of ‘atypical’ cases was recently reported by Nasr and colleagues – all had bright linear GBM staining for immunoglobulin on kidney biopsy, though none had detectable $\alpha 3(IV)NC1$ antibodies by commercial ELISA, and none had lung hemorrhage [128]. Most had had only mild renal insufficiency, though all had proliferative glomerular changes on renal biopsy, but without diffuse crescent formation. Treatment was with heterogeneous immunosuppression (and generally did not include plasma exchange), and both patient and renal survival at one year were favorable, at 93% and 85%, respectively. Of note, GBM staining was IgM dominant in two cases, and IgA dominant in another. In addition, half of the patients had restriction for either kappa or lambda lights on immunofluorescence testing, though none had glomerular capillary wall deposits on electron microscopy (that would be expected in proliferative GN with monoclonal immunoglobulin deposits; PGNMID), nor did they have identified features of an underlying plasma cell dyscrasia. A number of other case reports and small series have similarly described ‘atypical’ cases, with similarly indolent renal disease and seronegativity by conventional assay. One recent report describes a case of florid anti-GBM disease with kappa-light chain restriction on

GBM staining in association with a circulating paraprotein [129], thus suggesting that anti-GBM disease may occur within the spectrum of ‘monoclonal gammopathy of renal significance.’ A number of mechanisms for the unusual pattern of renal injury in these cases have been proposed, including differences in antibody isotype or subclasses, varied antigenic targets, and differential pathogenicity in antibodies related to their ability to fix complement or recruit inflammatory cells [130].

ANTI-GBM DISEASE AFTER ALEMTUZUMAB THERAPY

Secondary autoimmune phenomena after alemtuzumab, an anti-CD52 lymphocyte depleting treatment for relapsing-remitting multiple sclerosis (MS), are common [131]. Autoimmune thyroid disease occurred in up to 30% of patients in controlled trials, and there are case reports of both membranous nephropathy and anti-GBM disease following treatment [132, 133]. It has been proposed that T-cell reconstitution after alemtuzumab is driven largely by homeostatic expansion of cells that have escaped deletion (rather than by thymopoiesis), resulting in a T-cell pool that is enriched for autoreactive cells [134]. Anti-GBM disease has not been reported when alemtuzumab is used for other indications other than MS (e.g., renal transplantation), perhaps due to the use of maintenance immunosuppression, or due to the shared HLA susceptibilities in MS and anti-GBM disease. Careful monitoring of patients for renal pathology after treatment with alemtuzumab is needed in order to facilitate early detection and treatment [135]. We suggest conventional treatment for anti-GBM disease occurring in this setting.

ISOLATED PULMONARY INVOLVEMENT IN ANTI-GBM DISEASE

Presentation with isolated or predominant pulmonary involvement in anti-GBM disease is recognized, though uncommon, being estimated to occur in <10% of patients in larger series. Such cases are not extensively characterized, perhaps reflecting publication bias from renal centers, though there are small case series [136, 137]. Some patients may have mild urinary abnormalities and minor proliferative changes on renal biopsy, but with preserved excretory renal function, while others may have no clinical or histological evidence of renal inflammation. Renal biopsy, however, may still reveal linear deposits of immunoglobulin, including in those patients who are negative by serological assay. A small series from Sweden recently described four young female patients who presented with severe alveolar hemorrhage and favorable renal outcome, who were seronegative for circulating anti-GBM antibodies by conventional assay [138]. They were, however, found to have circulating IgG4 anti-GBM antibodies by dedicated ELISA, and this was confirmed on kidney biopsy. Together, these findings suggest that clinical presentation in anti-GBM disease may be influenced by differences in antibody subclass or antigen target, and highlight the need to consider variant anti-GBM disease in cases of ‘idiopathic’ pulmonary hemorrhage.

CONCLUSION

Despite its rarity, anti-GBM disease has been extensively studied, and it now serves as a model autoimmune disorder: it has a well-characterized autoantigen with defined epitopes; it demonstrates the directly pathogenic potential of specific autoantibodies; T-cell responses contribute to disease pathogenesis, both as orchestrators of the immune response and as effectors of tissue injury; and recent work sheds light on the molecular mechanisms via which HLA inheritance may confer autoimmune susceptibility. However, variant and atypical presentations demonstrate that anti-GBM disease cannot be regarded as a 'one-dimensional' entity [139], and that the mechanisms which induce the aberrant adaptive immune response directed to self-antigen are not fully understood and may not be common to all patients. Further insights into these inciting events and, given the extreme rarity of relapses, the mechanisms via which immune tolerance is reinstated as disease resolves, may have important therapeutic implications not just in anti-GBM disease, but also for a spectrum of autoimmune disorders in future. The abrupt clinical presentation of life-threatening lung hemorrhage and rapidly progressively glomerulonephritis, however, renders the disease of equal import to physicians as to immunologists, as early recognition and prompt initiation of immunosuppression and plasmapheresis is necessary to preserve kidney function and prevent mortality. Current treatment strategies, when introduced early enough, appear to be effective, though improved prognostic and therapeutic approaches are required for those presenting with advanced renal failure.

Chapter 209

SYSTEMIC VASCULITIS OF THE GASTROINTESTINAL TRACT

ABSTRACT

Systemic vasculitides are a cause of vascular inflammation throughout the body including the gastrointestinal tract. The nature of gastrointestinal (GI) involvement depends on the size and location of the affected vessels. Involvement of large vessels typically leads to downstream ischemia and tissue infarction. Medium vessel involvement can cause hemorrhage from ruptured aneurysms, downstream ischemia and tissue infarction. Small vessel involvement typically leads to ulceration, patchy infarction and bleeding. Severe GI involvement in systemic vasculitis confers a worse prognosis. Management of the underlying vasculitic process includes some form of immunosuppression however surgical intervention to manage intra-abdominal pathology caused by the vasculitic process may also be necessary. Revascularization procedures may be needed to manage aneurysm formation and to rescue ischemic tissue. This chapter reviews GI involvement in primary and secondary vasculitic diseases and outlines their management. Consideration will be given to GI tract complications due to immunosuppressive therapy for systemic vasculitis.

Keywords: systemic, vasculitis, gastrointestinal, autoimmunity

INTRODUCTION

The hallmark of vasculitis is inflammation in the blood vessels seen histologically as fibrinoid necrosis or in some cases granulomatous inflammation. Inflammation and occlusion of the vessel lumen of muscular arteries leads to downstream tissue ischemia and necrosis while focal involvement of the vessel wall can result in aneurysm formation and vessel rupture with catastrophic bleeding [1]. Vasculitis affects any part of the body depending on the blood vessel or vascular bed involved. In some vasculitides, gastrointestinal tract (GIT) involvement is common. In considering how different vasculitides can affect the GIT it is important to revisit the classification of vasculitis.

Vasculitis can be classified as primary or secondary in nature, and localized or systemic in its distribution and organ involvement. The 2012 Chapel Hill Consensus Conference (CHCC) [2] provides a useful nosology and definitions of the vasculitides based upon the caliber of the vessel involved and the associated clinicopathological features (Table 1). Primary systemic vasculitides occur as a primary process, whereas secondary vasculitides are secondarily associated with another underlying condition such as connective tissue disease, hypersensitivity reactions to drugs or infection. Localized or single organ vasculitides manifest symptoms confined to a single organ or to the skin whereas systemic vasculitides are characterized by constitutional symptoms and multiorgan involvement.

Overall, the extent and distribution of GIT involvement by the underlying vasculitic process, whether primary or secondary, depends mainly upon the size and location of affected vessels. A vasculitic cause for a given GIT disturbance should be suspected when unusual sites such as the stomach, duodenum, and rectum are involved by mesenteric ischemia along with systemic features or multi-organ involvement, particularly in young patients [3]. In a recent series reporting endoscopically confirmed upper GI involvement amongst 148 patients with vasculitis, IgA vasculitis was the most prevalent underlying vasculitic process (57%) followed by Takayasu arteritis (TA) (14%), microscopic polyangiitis (MPA) (10%) and polyarteritis nodosa (PAN) (7%) [4]. Notably, patients with Bechet disease (BD) were excluded from this study.

Table 1. Classification of vasculitis*

	Primary	Secondary
Large vessel	Giant cell arteritis	
	Takayasu arteritis	
Medium vessel	Polyarteritis nodosa	
	Kawasaki disease	
Small vessel	Henoch-Schonlein purpura	Systemic lupus erythematosus
	Granulomatosis with polyangiitis	Rheumatoid vasculitis
	Microscopic polyangiitis	Cryoglobulinemia
	Eosinophilic granulomatosis with polyangiitis	Other (drugs, infections, malignancy)

*Adapted from reference 13.

Acute mesenteric ischemia and tissue infarction secondary to vasculitis are well recognized [5-10]. Although relatively rare, vasculitic GIT involvement leading to acute abdominal pathology is potentially catastrophic and it is therefore important to promptly diagnose it in the appropriate clinical setting. Mesenteric vasculitis accounts for less than 5%

of all patients with chronic mesenteric ischemia [11], while other GIT manifestations of vasculitis include ulceration, submucosal oedema, hemorrhage, paralytic ileus, bowel obstruction and perforation [12].

This chapter will consider both primary and secondary vasculitides first giving a brief outline of the diseases followed by specific GIT involvement with consideration of the investigations, management and prognostic implications of GIT involvement. Treatment-related GIT morbidity will also be considered.

PRIMARY SYSTEMIC VASCULITIS

Large Vessel Vasculitides

Vasculitic involvement of large vessels leads to symptoms similar to mesenteric ischemia and may be difficult to differentiate from atherosclerotic disease when systemic features are absent or not apparent.

Takayasu Arteritis

Epidemiology

Takayasu arteritis involves large arteries and is pathologically characterized by granulomatous inflammation of the aorta and its major branches [13]. The disease, which has a female preponderance with a predominant age at onset of 10 to 40 years [14, 15], is rare but has an increased incidence in Asian, Mexican and Japanese populations [16].

Classification and Diagnostic Criteria

In 1990 the American College of Rheumatology (ACR) published criteria for the classification of TA [15], while other useful classification and diagnostic criteria were published in 1988 by Ishikawa [17], and later modified by Sharma and colleagues [18], both of which are shown in Tables 2 and 3.

Table 2. The American College of Rheumatology 1990 criteria for the classification of Takayasu arteritis*

Criteria	Definition
Age at disease onset <40 years	Development of symptoms or findings related to Takayasu arteritis at age <40 years
Claudication of extremities	Development and worsening of fatigue and discomfort in muscles of one or more extremity while in use, especially the upper extremities
Decreased brachial artery pulse	Decreased pulsation of one or both of brachial arteries
BP difference >10mmHg	Difference of >10mmHg in systolic blood pressure between arms
Bruit over subclavian arteries or aorta	Bruit audible on auscultation over one or both subclavian arteries or abdominal aorta
Arteriogram abnormality	Arteriographic narrowing or occlusion of the entire aorta, its primary branches, or large arteries in the proximal upper or lower extremities, not due to arteriosclerosis, fibromuscular dysplasia or similar causes; changes usually focal or segmental

For purposes of classification, a patient shall be said to have Takayasu arteritis if at least three of these six criteria are present. The presence of any three or more criteria yields a sensitivity of 90.5% and a specificity of 97.8%.

*Adapted from reference 15.

Table 3. Ishikawa criteria for diagnosis of Takayasu arteritis*

Criteria	Definition
Three Major Criteria	
1. Left mid subclavian artery lesion	The most severe stenosis or occlusion present in the mid portion from the point 1 cm proximal to the vertebral artery orifice up to that 3 cm distal to the orifice determined by angiography
2. Right mid subclavian artery lesion	The most severe stenosis or occlusion present in the mid portion from the right vertebral artery orifice to the point 3 cm distal to the orifice determined by angiography
3. Characteristic signs and symptoms of at least 1 month duration	These include limb claudication, pulselessness or pulse differences in the limbs, an unobtainable or significant blood pressure difference (> 10 mmHg systolic blood pressure difference in limb), fever, neck pain, transient amaurosis, blurred vision, syncope, dyspnea or palpitations
Ten Minor Criteria	
1. High ESR	Unexplained persistent high ESR >20 mm/hour (Westergren) at diagnosis or presence of the evidence in patient's history
2. Carotid artery tenderness	Unilateral or bilateral tenderness of common carotid arteries on palpation. Neck muscle tenderness is unacceptable
3. Hypertension	Persistent blood pressure >140/90 mmHg brachial or >160/90 mmHg popliteal
4. Aortic regurgitation or annuloaortic ectasia	By auscultation, angiography or Doppler echocardiography. By angiography or two-dimensional echocardiography
5. Pulmonary artery lesion	Lobar or segmental arterial occlusion or equivalent determined by angiography or perfusion scintigraphy, or presence of stenosis, aneurysm, luminal irregularity or any combination in pulmonary trunk or in unilateral or in bilateral pulmonary arteries determined by angiography
6. Left mid common carotid lesion	Presence of the most severe stenosis or occlusion in the mid portion of 5 cm in length from the point 2 cm distal to its orifice determined by angiography
7. Distal brachiocephalic trunk lesion	Presence of the most severe stenosis or occlusion in the distal third determined by angiography
8. Descending thoracic aorta lesion	Narrowing, dilatation or aneurysm, luminal irregularity or any combination determined by angiography. Tortuosity alone is not acceptable
9. Abdominal aorta lesion	Narrowing, dilatation or aneurysm, luminal irregularity or aneurysm combination
10. Coronary artery lesion	Documented on angiography below the age of 30 years in the absence of risk factors like hyperlipidemia or diabetes mellitus

The presence of two major, one major and three minor, or four minor criteria suggests a high probability of TA.

*Adapted from reference 18.

Clinical Features

Constitutional symptoms including fatigue, weight loss, arthralgia and fever are common in TA particularly in the early stages of the disease. Specific symptoms such as claudication of extremities, headaches, presyncope, syncope, and angina depend on the affected vessels involved [19] (Tables 2 and 3).

Imaging

Conventional angiography is the gold standard for vascular assessment in TA with common sites of involvement located along the middle and proximal parts of the left subclavian and carotid arteries [19]. A study of 60 patients with TA found the abdominal aorta to be involved in 47% of patients employing conventional angiography, with the vast majority of abnormalities due to stenotic rather than aneurysmal vascular changes [19]. Involvement of the abdominal aorta occurs in the descending aortic syndrome that can lead to mesenteric vasculitis in TA. Mesenteric vessel involvement is seen in up to 18% of patients with TA studied by conventional angiography [3, 16, 19]. Although mesenteric vascular involvement of TA is relatively common on radiological assessment, symptomatic GIT

involvement on presentation is rare with one study looking at TA in children reporting only 9% presenting with abdominal symptoms [20].

Due to the invasive nature of conventional angiography, computed tomographic angiography (CTA), magnetic resonance angiography (MRA), and positron emission tomography (PET) have been employed in the evaluation of TA, particularly when therapeutic intervention is not anticipated. CTA averts the risk of arterial puncture, accurately depicts luminal changes, and provides useful information on mural changes such as arterial wall thickening and mural thrombi that might otherwise not be appreciated on conventional angiography [20]. MRA avoids the risks of radiation and the need for intravenous injection of iodinated contrast, while providing a generalized arterial survey similar to that of CTA. PET may have a role in differentiating between active lesions and scar formation along areas of vascular wall thickening [21]. A recent meta-analysis found PET to have a sensitivity of 87% and specificity of 73% for assessing TA disease activity [22].

Gastrointestinal Involvement

GI involvement is manifested by mesenteric artery ischemia presenting mainly as postprandial mesenteric angina that may require revascularization. Diarrhea and GI haemorrhage commonly occur due to mesenteric vessel involvement. Rarely this may culminate in acute intestinal infarction which is catastrophic when it occurs [16, 19]. There is a single case report of TA initially presenting as intestinal gangrene secondary to intestinal infarction [23]. Aneurysmal dilatation is a recognized complication of TA particularly along the descending thoracic and abdominal aorta [18]. There is a single report of a patient with TA manifesting as primary aortic-esophageal fistula formation associated with a saccular aneurysm of the proximal descending aorta [24].

Treatment

Treatment in TA can be divided into pharmacological therapy aimed at suppressing inflammation, and revascularization. Corticosteroids are the mainstay of pharmacotherapy although methotrexate, azathioprine, anti-tumor necrosis factor (TNF) therapy, and cyclophosphamide have all been used in patients with TA refractory to corticosteroids [25-27].

Revascularization treatment in TA is delivered by open conventional bypass grafting or endovascular means including, percutaneous transluminal angioplasty with or without stent insertion [28]. Advances in interventional radiology have led to more widespread use of endovascular techniques in the management of high-risk patients. There are several patient reports and case series of TA in the literature describing the successful outcome of endovascular repair of challenging stenotic and aneurysmal lesions [29-33]. Comparisons of the surgical versus endovascular management of lesions of the abdominal aorta in TA shows that the risk of complication, especially restenosis, is higher with endovascular than surgical intervention [34, 35]. A multicenter retrospective study found that over a median follow up of 6.5 years the risk of complications following endovascular repair was 50% compared to 37.5% after surgical repair [35]. Multivariable analysis revealed that patients with TA and evidence of systemic inflammation at the time of revascularisation, as defined by an erythrocyte sedimentation rate (ESR) > 30 mm/hour and C-reactive protein (CRP) level > 6 mg/L, were 7-fold more likely to develop post-procedural complications including restenosis.

Giant Cell Arteritis

Epidemiology and Classification

Giant cell arteritis (GCA) is characterized by granulomatous inflammation that predominantly affects the thoracic aorta and its branches. The age of onset is greater than 50 years with an increased incidence in those 70 to 80 years of age, and a higher incidence in Northern Europeans and North Americans of Scandinavian descent compared to other ethnic groups [36]. The 1990 ACR criteria are shown in Table 4. It should be noted that these criteria were intended for the classification not the diagnosis of GCA [37].

Table 4. The American College of Rheumatology 1990 criteria for the classification of giant cell arteritis*

Criteria	Definition
Age at disease onset >50 years	Development of symptoms beginning at age 50 years or older
New headache	New onset of or new type of localized pain in the head
Temporal artery abnormality	Temporal artery tenderness on palpation or decreased pulsation, unrelated to arteriosclerosis of cervical arteries
Elevated ESR	ESR > 50mm in the 1st hour by the Westergren method
Abnormal artery biopsy	Biopsy specimen with artery showing vasculitis characterized by a predominance of mononuclear cell infiltration or granulomatous inflammation, usually with multinucleated giant cells

For the purposes of classification at least 3 criteria must be fulfilled; sensitivity 93.5%, specificity 91.2%.

*Adapted from reference 37.

Clinical Features

The commonest manifestation of GCA is headache followed by scalp tenderness, jaw claudication and visual disturbances; constitutional symptoms such as fever, fatigue and weight loss are also prominent [5, 36]. Approximately 20% of patients with GCA develop clinical manifestations reflecting large vessel involvement including aneurysmal and stenotic lesions of the abdominal aorta which in turn can lead to GI sequelae [36].

Gastrointestinal Involvement

GCA can affect both the liver and the bowel. Asymptomatic involvement of the liver, as manifested by elevated serum alkaline phosphatase and transaminase levels, is reported in up to 50% of patients with GCA [38]. The mechanism leading to liver enzyme derangement is not fully understood however when liver biopsy has been conducted in cases of symptomatic liver involvement, this has demonstrated granulomatous inflammation of medium-sized arterioles within the portal tracts [39]. Whilst clinically evident mesenteric involvement is uncommon, occult radiographic manifestations are noted on arteriography in 18% of patients with GCA [5, 40, 41].

In total there have been 11 reported cases of GCA with bowel involvement, mainly in the form of mesenteric ischemia. Of 11 patients with bowel involvement in GCA, nine were biopsy-proven [5, 8, 42-49], of whom four presented with abdominal symptoms in the absence of symptoms of temporal arteritis. Temporal artery biopsy was positive in only two of the four patients suggesting a negative temporal artery biopsy may not be able to reliably exclude GCA involving the mesenteric vasculature [5].

Treatment

The mainstay of treatment in GCA is high dose corticosteroids to induce remission. Methotrexate is recommended as an adjunctive therapy, while TNF- α and interleukin (IL)-6 inhibitors may have a role in the treatment of relapsing or refractory disease [36, 50-52]. The IL-6 inhibitor tocilizumab has shown particular promise with a recent phase three randomized controlled trial demonstrating significant improvement in sustained remission rates and steroid sparing effects in both newly diagnosed and relapsing GCA [52]. For occlusive disease surgical revascularization is indicated. Comparison of the outcomes of 15 patients undergoing open revascularization for occlusive mesenteric vasculitis secondary to TA, PAN, GCA and indeterminate vasculitis compared to 163 patients undergoing open operations for atherosclerotic disease [11] showed that both groups had similar freedom from mesenteric symptoms and primary graft patency. In this study 8 of the 15 patients with vasculitic disease had active inflammation at the time of intervention and by the end of follow up (mean follow-up 41 months) 14 of 15 patients remained asymptomatic suggesting that surgical revascularization even during active disease is an effective treatment for occlusive mesenteric vasculitis.

MEDIUM VESSEL VASCULITIDES

Ischemia and infarction in dependent organs associated with bleeding in the GIT and within the abdominal cavity, and aneurysm formation occurs in the context of vasculitic involvement affecting medium size vessels typified by polyarteritis nodosa (PAN) and Kawasaki disease (KD).

Polyarteritis Nodosa

Epidemiology

This systemic necrotizing vasculitis is characterized by fibrinoid necrosis that typically involves medium sized arteries [53]. It typically affects middle-age and older individuals with a peak onset in the 6th decade of life. Hepatitis B virus (HBV) infection is associated in up to one third of patients with PAN and is an important consideration with regards to treatment and prognosis [54].

Classification and Diagnosis

Diagnosis of PAN entails the integration of clinical, angiographic and biopsy findings (table 5). Angiographic evaluation is very helpful in the diagnosis and management of PAN. The gold standard is conventional arteriography, with increasing utilization of both CTA and MRA. The typical findings are multiple aneurysms less than 1 cm in diameter that are most often found in the distribution of the renal and mesenteric arteries, the superior mesenteric artery being the commonest vessel involved in some series [16, 55]. The lesions classically affect branch points and the bifurcation of arteries due to segmental erosion and inflammation that weakens the arterial wall [3]. These aneurysms are not pathognomonic for the condition

as they can be found in granulomatosis with polyangiitis (GPA) as well as in systemic lupus erythematosus (SLE) [56].

Table 5. The American College of Rheumatology 1990 criteria for the classification of polyarteritis nodosa*

Otherwise unexplained weight loss of > 4 kg
Presence of livedo reticularis
Testicular pain or tenderness
Myalgia (excluding that of the shoulder hip and girdle) or weakness
Mononeuropathy or polyneuropathy
New onset rise in diastolic blood pressure >90 mmHg
Elevated levels of serum blood urea nitrogen (>40 mg/dL or >14.3 mmol/L) or creatinine (>1.5 mg/dL or >132 µmol/L)
Evidence of hepatitis B virus infection via serum antibody or antigen serology
Characteristic arteriographic abnormalities not resulting from non-inflammatory disease processes
A biopsy of medium or small sized artery containing polymorphonuclear cells

For the purposes of classification at least 3 criteria must be fulfilled; sensitivity 82%, specificity 87%.

*Adapted from reference 53.

Clinical Features

Clinical features of PAN include constitutional symptoms such as malaise, weight loss and fever as well as specific symptoms and signs reflecting the extent of multi-system involvement [57] (Table 6).

Table 6. Clinical features of polyarteritis nodosa*

Manifestation	Specific Problems	Frequency (%)
Systemic symptoms	Fever, malaise, weight loss	80
Neuropathy	Mononeuritis multiplex, polyneuropathy	75
Arthralgia and/or myalgia	Articular and/or diffuse extremity pain	60
Cutaneous	Livedo reticularis, purpura, ulcers	50
Renal disease	Elevated creatinine, hematuria, glomerulonephritis	50
Gastrointestinal symptoms	Abdominal pain, rectal bleeding	40
Hypertension	New onset	35
Respiratory manifestations	Infiltrates, nodules, cavities	25
Central nervous system disease	Stroke, confusion	20
Orchitis	Testicular pain, swelling	20
Cardiac involvement	Cardiomyopathy, pericarditis	10
Peripheral vascular disease	Claudication, ischemia, necrosis	10

*Adapted from reference 57.

Gastrointestinal Involvement

GI involvement occurs in 14 to 65% of patients with PAN affecting both the bowel and hepatobiliary system [55]. Abdominal pain is the most commonly reported GI symptom in PAN. Bowel manifestations of PAN include ulceration, obstruction, infarction, and perforation and hemorrhage that can affect the stomach, small and large bowel and the appendix with the small bowel being most commonly affected [56-58]. Bowel involvement can arise from stenotic lesions that lead to bowel wall ischemia and aneurysm formation that results in hemorrhage. Necrosis of the bowel wall with the potential for subsequent perforation can develop if systemic inflammation gives rise to transmural ischemia and

confers a poor prognosis [55]. Liver involvement occurs in 16 to 56% of patients and can manifest as fibrinoid necrosis of the liver, hepatic artery aneurysms, liver infarction or hepatolithiasis [55, 59, 60]. Small vessel vasculitis of the arteries that supply the bile ducts and gall bladder can lead to intrahepatic sclerosing cholangitis, bile duct stricture, cholecystitis, and hemobilia. Pancreatic involvement can also occur in the form of pancreatitis, pseudocysts and pancreatic insufficiency [55]. Hepatobiliary involvement is potentially life threatening with death due to rupture of the hepatic artery reported [61].

A retrospective analysis of 54 patients with PAN reported GI involvement in 24 (44%) with two-thirds noting abdominal pain at presentation, while all others had abdominal pain at some point in their illness. Of the 24 patients with GIT involvement at presentation 13 (54%) developed an acute abdomen secondary to bowel infarction, perforation, acute cholecystitis, gall bladder infarction, aneurysmal rupture of hepatic, splenic or renal arteries, or bleeding from perforated gastric ulcers [62]. Multiple aneurysm formation is a defining feature of PAN and is noted in 50 to 70% of those with involvement of the GIT with the hepatic artery affected in 50 to 60%; splenic artery in 45%; and pancreatic artery in 25 to 35% [62-64]. Massive internal hemorrhage due to rupture of an aneurysm within the intestine is rare but nonetheless carries a high mortality of up to 75% [64-67].

Treatment

The mainstay of treatment for mild PAN is corticosteroids. However GI involvement constitutes severe disease, which has been shown to have a better outcome when treated with a combination of cyclophosphamide and corticosteroids [68]. PAN secondary to HBV infection is treated with two weeks of corticosteroids followed by antiviral treatment combined with plasma exchange. Those so treated with antiviral therapy do not experience HBV relapses once viral replication has stopped and seroconversion has been achieved [54].

Occlusive mesenteric disease can be managed successfully with open revascularization [11]. Percutaneous endovascular trans-catheter embolization is increasing used to deal with ruptured visceral artery aneurysms associated with PAN [69]. If tissue necrosis or gangrene occurs due to infarction then definitive surgical management in the form of resection is indicated [70].

Kawasaki Disease

Epidemiology and Clinical Features

Kawasaki disease (KD) is one of the commonest childhood vasculitides with a particularly high incidence and prevalence in East Asia. Most patients have disease onset before 5 years of age with a peak incidence at 30 months [71]. The diagnosis is confirmed by the presence of fever for more than five days, and the presence of four of the following five diagnostic criteria: bilateral conjunctival injection; changes of the mucous membranes of the upper respiratory tract including injected pharynx, fissured lips or strawberry tongue; polymorphous rash; limb changes including peripheral edema, erythema, or periungual desquamation; and cervical adenopathy. Untreated KD is a self-limiting disease that lasts for 10 to 12 days; however, coronary artery aneurysms develop in 20% to 25% of patients with significant associated morbidity and mortality [71].

Gastrointestinal Involvement

GI involvement is relatively uncommon but tends to involve the gallbladder and the liver leading to acute non-calculous distension of the gallbladder (gallbladder hydrops), hepatic dysfunction with elevated serum transaminase concentrations and febrile cholestatic jaundice [73-72]. Presentation with an acute abdomen was reported in 4.6% of children with KD [73] due to vasculitic appendicitis, paralytic ileus, or hemorrhagic duodenitis. KD may be an important cause of febrile cholestatic jaundice with up to 21% of febrile cholestatic cases overall being attributed to KD in a recent series [74]. A high index of suspicion for KD should therefore be maintained for children presenting with febrile cholestatic jaundice.

Treatment

Treatment of KD with aspirin and intravenous immunoglobulin (IVIg) reduces the incidence of coronary artery complications compared with aspirin alone [75]. There are no studies that have investigated the GI outcomes or GI response to treatment in KD. Interestingly, elevated bilirubin and gamma-glutamyl transpeptidase (γ GT) have been associated with non-responsiveness, defined by persistent fever, to IVIg treatment [76].

SMALL VESSEL VASCULITIDES

Involvement of small vessels by vasculitis can lead to ulceration, erosions, strictures and occasionally perforation.

IgA Vasculitis/Henoch-Schönlein Purpura

Epidemiology and Clinical Features

IgA vasculitis/Henoch-Schönlein purpura (IgAV/HSP) is a small vessel vasculitis characterized by a leukocytoclastic vasculitis and deposition of IgA-containing immune complexes. It is the commonest form of systemic vasculitis in children with a peak incidence at four to six years of age, although adult patients have been described [77]. It is usually self-limiting and characterized by the tetrad of palpable purpura in the absence of thrombocytopenia or coagulopathy; arthritis or arthralgia; abdominal pain; and renal involvement. The disease follows a more severe course when it presents in adults with a higher incidence of renal impairment and end-stage renal disease [78].

Diagnosis

Although childhood IgAV/HSP is typically clinically diagnosed, adults generally undergo skin or renal biopsy for tissue confirmation. Imaging can be helpful in assessing the GI manifestations of IgAV/HSP especially ultrasonography for the detection of increased bowel wall thickness, hematomas, and intussusception [79].

Gastrointestinal Involvement

GI involvement occurs in 50% of children with IgAV/HSP and can affect the hepatobiliary system or the bowel in a number of ways [16]. Bowel manifestations include;

intussusception [80, 81], intestinal ischemia and infarction, intestinal perforation, gastrointestinal hemorrhage and purpura [82-88] esophageal necrosis [89], ileitis and ileal stricture [90], fistulae formation and acute appendicitis [91]. Hepatobiliary features include; pancreatitis [92] and hydrops of the gallbladder [93]. Functional GIT disorders such as irritable bowel syndrome are reported to have a higher prevalence in children with IgAV/HSP despite resolution of acute flares and are associated with increased steroid use [94]. GI symptoms tend to occur within eight days of the appearance of the rash although they may precede the rash. Abdominal pain is seen in 60-70% of children with IgAV/HSP and is thought to be caused by submucosal bleeding and oedema [95]. A 2001 Spanish study [96] noted that 16.7% of affected children presented with abdominal pain as the solitary symptom; 7.6% presented with abdominal pain and a rash, and 2.6% with abdominal pain, rash and joint pains. Altogether, 70.5% of patients progressed to mesenteric ischemia, and 30.8% had evidence of GI bleeding. The commonest GI manifestation in childhood IgAV/HSP was intussusception. Although the prognosis of IgAV/HSP in children is good, adult onset IgAV/HSP often has a less favorable outcome [78]. In adults severe GI involvement, manifested by abdominal pain and bleeding [97-99], can be associated with a fatal outcome [100-102].

Predictive Markers in Gastrointestinal IgAV/HSP

Due to the high frequency of GI complications in IgAV/HSP and its potentially serious complications predictive markers have been sought. Serum amyloid A and faecal calprotectin have both been demonstrated to be significantly increased in GIT IgAV/HSP compared to non GIT IgAV/HSP [103, 104]. In a study of 70 patients with IgAV/HSP compared to controls serum amyloid A levels were significantly increased in cases of IgAV/HSP with GIT involvement but were not increased in renal or joint involvement [103]. Faecal calprotectin is a heterodimer of calcium binding proteins and elevated stool levels are associated with GI inflammation [105]. Faecal calprotectin is a useful screening tool in the diagnostic workup of inflammatory bowel disease [106]. In a study of 66 children with IgAV/HSP faecal calprotectin levels were found to be significantly different between groups with and without GIT involvement as well as being significantly different between groups with and without renal involvement [104].

Hematological ratios such as neutrophil-lymphocyte ratio and platelet-lymphocyte ratio have been associated with GIT IgAV/HSP and have been suggested as screening tools for GI involvement [107, 108].

Personalised medicine and genomics may be another approach to risk stratification of GIT IgAV/HSP. A Chinese study has reported an association between platelet-activating factor acetyl-hydrolase gene polymorphisms and GI bleeding [109]. None of these predictive markers are in routine use and further prospective studies with larger numbers are needed to confirm these findings before they could be used in routine clinical practice.

Treatment

Management of IgAV/HSP is largely supportive with administration of non-steroidal anti-inflammatory drugs and corticosteroids for severe abdominal pain and joint involvement.

There is no convincing evidence to suggest that early use of corticosteroids reduces the risk of renal involvement or acute GI complications [110]. Plasma exchange, IVIg, mycophenolate mofetil (MMF) and single dose cyclophosphamide have all been reported in the management of GIT IgAV/HSP [111-114]. In one case series of eight children with severe GIT IgAV/HSP involvement six responded to IVIg with two having a further relapse both of which responded to a second dose of IVIg [113]. Plasma exchange has also been reported to improve disease control in a case series [111]. The management of intussusception in children with IgAV/HSP often requires surgical correction [115].

ANCA-Associated Vasculitis

Epidemiology and Classification

The antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are a group of autoimmune inflammatory conditions comprising GPA, microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA) that predominantly affect small- to medium-sized blood vessels.

The individual annual incidence of the AAV is 10 to 20 per million population with a peak age of onset in the seventh and eighth decades [118]. Table 7 lists classification criteria for the AAV [13].

Clinical Features

The clinical features of AAV include constitutional symptoms including malaise, joint pains and weight loss, and other symptoms and signs depending on the extent of systemic involvement. The upper and lower airways, skin, peripheral and central nervous system, as well as the kidneys, are typically involved organ systems [119].

Table 7. Chapel Hill consensus conference on the nomenclature of systemic vasculitis: Definitions

Granulomatosis with polyangiitis (Wegener’s) (GPA)	Granulomatous inflammation involving the respiratory tract, and necrotizing vasculitis affecting small to medium-sized vessels (e.g., capillaries, venules, arterioles, and arteries). Necrotizing glomerulonephritis is common
Microscopic polyangiitis (MPA)	Necrotizing vasculitis, with few or no immune deposits, affecting small vessels (i.e., capillaries, venules, or arterioles). Necrotizing arteritis involving small and medium sized arteries may be present. Necrotizing glomerulonephritis is very common. Pulmonary capillaritis often occurs
Eosinophilic granulomatosis with polyangiitis (Churg–Strauss syndrome) (EGPA)	Eosinophil-rich and granulomatous inflammation involving the respiratory tract, necrotizing vasculitis affecting small to medium-sized vessels, and associated with asthma and eosinophilia

*Adapted from reference 13.

Gastrointestinal Involvement

Abdominal pain and diarrhea in EGPA results from eosinophilic gastroenteritis and mesenteric vasculitis leading to bowel ulceration, ischemia, and perforation [12]. Up to one third of patients with EGPA manifest GI involvement with severe involvement associated with increased mortality [120]. The potential for GI involvement is varied and can include

upper or lower GI bleeding, perforation of the esophagus, stomach, small and large intestine, bowel ischemia, bowel obstruction secondary to stenosis, colitis and cholecystitis; the commonest manifestation is abdominal pain [16, 116].

GI involvement in GPA is reported in 0-26% of patients [117-122]. Seventy-one percent of GPA patients who ever have GIT involvement will have it at presentation [123]. Abdominal pain, diarrhea and blood loss are the commonest findings. More severe GI involvement can lead to ulceration, massive hemorrhage, ischemia of the small and large intestine or bowel perforation [3, 117, 124-128]. Isolated granulomatous pancreatic lesions, presenting with painless jaundice, pancreatitis and abdominal pain, have been reported in GPA, often being misdiagnosed radiologically as adenocarcinoma [129-131].

GI involvement is uncommon in MPA but can include hemorrhage, ulceration, and intestinal ischemia, in some cases as the presenting feature of disease [132-135]. Life-threatening gallbladder bleeding secondary to vasculitic involvement of the gallbladder has been reported [136].

The French Vasculitis Study Group (FVSG) developed a Five Factor Score (FFS; Table 8) to predict outcomes in patients with PAN and EGPA. The presence of one or more factors predicted a higher mortality [137]. In a retrospective analysis of 1108 consecutive patients with PAN, MPA, EGPA and GPA registered in the FVSG database; age >65 years, cardiac symptoms, gastrointestinal involvement and renal insufficiency, which were all independently associated with a higher five year mortality [138]. More recently, GIT involvement in EGPA was associated with more frequent relapses of disease but had no association with overall survival [139].

Treatment

Management of AAV entails induction of disease remission followed by maintenance treatment and therapy directed at disease relapses. Different immunosuppressive agents can be used depending on disease severity ranging from methotrexate for localized and early systemic disease, to a combination of high dose corticosteroids, plasma exchange and cyclophosphamide or rituximab in severe life-threatening disease [140]. Where GI involvement has been complicated by large GI hemorrhage definitive intervention in the form of transarterial embolization or surgical intervention has been successful [128, 141].

Table 8. The five factor score*

	Factor	Definition
1	Renal involvement	Proteinuria >1g/24 hours
2	Renal impairment	Serum creatinine >1.582 mg/dl
3	Gastrointestinal involvement	Presence of any of the following: bleeding, perforation, infarction pancreatitis
4	Central nervous system involvement	
5	Cardiac involvement	Presence of cardiomyopathy

*Adapted from reference 138.

SECONDARY VASCULITIDES

Systemic Lupus Erythematosus

Systemic lupus erythematosus (SLE) is a systemic autoimmune condition that can affect any part of the body and GIT. SLE can cause lupus mesenteric vasculitis which can affect any part of the GIT but shows a predilection for the superior mesenteric artery [3]. Mesenteric vasculitis is reported in 0.2-9.7% of patients with SLE and affects around 60% of SLE patients presenting with abdominal pain [142]. The underlying pathogenesis arises from complement activation, immune complex deposition and thrombotic processes [142]. Ultimately this leads to ulceration, bleeding, stricture formation, and perforation resulting from tissue ischemia and infarction [143-146]. Rarely mesenteric vasculitis can be the presenting feature of SLE [145, 146]. GI involvement in SLE is generally associated with increased mortality, in some case series being as high as 50% [147]. Mesenteric vasculitis is generally treated initially with high dose intravenous methylprednisolone then with a tapering regime of oral corticosteroid [148]. Cyclophosphamide has also been reported to be effective [149].

VARIABLE VESSEL VASCULITIS

Behçet Disease

Behçet disease is a non-specific necrotizing vasculitis that affects multiple organs and blood vessels of all sizes. It is classically characterized by oro-genital ulceration, ocular disease, skin lesions and a positive pathergy test. BD has a prevalence of between 3.8-420 per 100000 population, and is most prevalent in countries along the old Silk Road such as Turkey [150]. GI involvement occurs in 2.8 to 60% of patients [150]. GIT involvement frequently mimics inflammatory bowel disease with features such as diarrhea, abdominal pain, rectal bleeding and endoscopic findings including mucosal ulceration with a preference for the ileocecal region and esophagus [12]. The GIT features of BD arise from large vessel vasculitis resulting in ischemia and infarction or from neutrophilic phlebitis leading to mucosal ulceration [151, 152]. Ulceration is often deep and can penetrate through the bowel wall leading to perforation, hemorrhage and fistula formation [153-155]. The most common hepatic manifestation of BD is Budd-Chiari syndrome, seen in 1.3-3.2% of patients, which can result in portal hypertension, ascites, varices and liver failure [150]. It is associated with significant mortality, one study reporting a mean survival of 10.4 months [156]. Other rare GIT complications of BD include carotid-esophageal fistula, aortic pseudoaneurysm rupture into the colon and pancreatitis [157-159].

Disease Monitoring

Intestinal BD can be monitored clinically with the Disease Activity Index for Intestinal BD (DAIBD), categorizing activity as quiescent, mild, moderate and severe [160]. Fecal Calprotectin has been shown to be raised in intestinal BD and correlate with disease severity; this could potentially become a predictive marker for intestinal BD [161].

Treatment

There is no universally accepted treatment regime, however 5-ASA and sulfasalazine have been the mainstay of treatment for mild to moderate disease and corticosteroids for severe disease or to induce remission [162, 163]. Azathioprine, anti-TNF therapy, thalidomide and methotrexate have also been used successfully in intestinal BD [164-166]. For Budd-Chiari Syndrome the mainstay of management is cyclophosphamide and corticosteroids whilst anticoagulation remains controversial [167]. Surgical intervention is generally used for uncontrolled GI bleeding and perforation [168]. Endoscopic intervention has been used for ulcer related GI bleeding [169]. Large vessel involvement can be treated via open surgical techniques or via the endovascular approach [170].

Other Secondary Vasculitides

GI complications occur in other autoimmune conditions such as rheumatoid arthritis (RA) and mixed connective tissue disease (MCTD) due to secondary vasculitis. In patients with RA vasculitis, up to 38% of cases have involvement of the mesenteric vessels leading rarely to ischemic ulceration and bowel perforation [171]. Secondary vasculitis leading to GI involvement in MCTD is rare and occurs in the form of small and large bowel ulceration and perforation [172, 173] as well as fatal hemorrhage [174]. Vasculitic GI manifestations occur in patients with Hepatitis C virus infection, as well as non-infectious mixed cryoglobulinemic vasculitis, ranging from abdominal pain to GI bleeding, infarction, duodenitis, hepatic and mesenteric vasculitis and perforation. GI perforation is associated with increased mortality [175-177]. In addition, GI involvement has been described in vasculitis secondary to the drugs propylthiouracil [178], hydroxyurea [179] and cocaine [180], or infection associated with cytomegalovirus (CMV) [181].

Urticarial vasculitis (UV) is a rare small vessel vasculitis thought to be secondary to immune complex deposition into the blood vessel wall. Clinical features include urticarial rash, angioedema and tissue ischemia. The etiology of UV is usually idiopathic however; it can also be secondary to autoimmune disease, paraneoplastic disease, drug reactions and infections [182]. UV secondary to infection has been reported to present as circumferential duodenitis and ulceration secondary to duodenal ischemia [183].

Treatment-Related GI Side Effects

As the treatment of vasculitis often involves immunosuppression with drugs such as corticosteroids, cyclophosphamide, azathioprine, methotrexate and biological therapies such as rituximab, treatment-related morbidity of the GI tract must be considered. Reactivation of CMV can lead to GI inflammation in the context of immunosuppression. Symptoms of abdominal pain, diarrhea and bleeding, as well as endoscopic signs of erythema, nodules and ulceration, are non-specific but similar to those of vasculitis [12]. It is very important to secure the diagnosis with biopsy specimens and peripheral blood CMV viral load. CMV disease usually responds to anti-viral therapy. Candida involvement of the oral cavity and the esophagus is a recognized complication of high-dose corticosteroid treatment. British Society

of Rheumatology Guidelines for the management of ANCA-associated vasculitis recommend that anti-fungal prophylaxis should be considered in patients receiving immunosuppressive therapy [140, 179]. However, according to a recent meta-analysis there is no clear evidence that the use of topical anti-fungal preparations such as nystatin is effective in preventing fungal colonization and infection in immunosuppressed patients [184]. Finally, corticosteroids and NSAID can lead to gastroduodenal ulceration as well as small and large intestine enteropathy [12].

CONCLUSION

GI involvement in vasculitis largely reflects the size of the blood vessel involved. Large vessel involvement may lead to stenotic lesions manifesting as ischemia or infarction of large, but often unusual segments of the GI tract. Medium vessel involvement is typified by aneurysmal as well as stenotic disease that can produce ischemia or infarction and bleeding whilst small vessel disease can present with abdominal pain, patchy ulceration, infarction and bleeding as well as intestinal perforation. Hepatobiliary and pancreatic involvement can occur and represent common GIT manifestations in some vasculitides. Treatment is aimed at controlling the underlying vasculitic process with immunosuppression although open surgical or endovascular therapy is important in the management of mesenteric vasculitis. Severe gastrointestinal involvement in vasculitis is associated with a higher mortality.

Chapter 210

RHEUMATOID ARTHRITIS VASCULITIS

Elana J. Bernstein, MD, MSc and Robert F. Spiera*, MD

The Scleroderma, Vasculitis and Myositis Center, Department of Medicine,
Division of Rheumatology, The Hospital for Special Surgery, New York, NY, USA

ABSTRACT

Rheumatoid arthritis is a systemic autoimmune disease characterized by inflammatory synovitis. The presence of fever, weight loss, digital infarcts, deep cutaneous ulcers, mononeuritis multiplex, peripheral gangrene, and other extra-articular complications suggest rheumatoid vasculitis. It is confirmed by the presence of necrotizing arteritis in a biopsy of involved skin, nerve or muscle tissue. Accurately recognized and properly treated with immunosuppressant and biological therapies, the morbidity and damage related to rheumatoid vasculitis can be mitigated. Thus, it is important to consider the diagnosis in any patient with RA in whom features emerge that could suggest the presence of arteritis. This chapter considers the epidemiology, clinical and laboratory manifestations, histopathology, and management of rheumatoid vasculitis.

Keywords: rheumatoid, vasculitis, classification, clinical, pathology, treatment

INTRODUCTION

Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammatory synovitis. An estimated 1,293,000 adults ≥ 18 year of age in the United States have RA representing about 0.6% of the adult population. Rheumatoid vasculitis (RV) is suggested by the presence of fever, weight loss, digital infarcts, deep cutaneous ulcers, mononeuritis multiplex, peripheral gangrene, and other extra-articular complications extra-articular (ExRA) complications, including necrotizing vasculitis, the initial histopathologic manifestations of which are generally found in a biopsy of skin, nerve and muscle tissue in

* Corresponding Author's Email: Spierar@hss.edu.

the majority of affected patients. While not strikingly different from classical or definite RA, those with RV have a reduced survival compared to the general population that is immediately evident and continues for up to six years [1, 2]. Vasculitis is a particularly significant ExRA manifestation, as it typically requires an escalation of immunosuppressive therapy at a time when patients may have already accrued significant disease-related tissue damage and therapy-related complications. It is important to consider RV because unrecognized and therefore untreated, the morbidity of this RA feature is substantial. This chapter discusses the epidemiology, clinical manifestations, histopathology, and treatment of RV.

HISTORICAL ASPECTS

The earliest reported patients with RA were children described in 1951 by Pirani and Bennett [3] with particularly severe RA progressing from childhood. The first patient was ill for four decades with numerous exacerbations and rare remissions with progressive limitation of the joints and a diagnosis of Still's disease that emerged into chronic disseminated RA before he died. Postmortem examination was notable for severe deforming RA and ankylosis, with left cerebellar hemorrhage, atrophy of bone, skin and muscle; healed glomerulonephritis and marked inflammatory spinal arachnoiditis with splenic follicular necrosis. The second patient presented at age 22 years after many years of disability unable to walk bedridden when he died. Postmortem examination was notable for severe deforming RA and ankylosis with widespread polyarteritis nodosa (PAN). A third patient developed progressive joint deformities from age 17 months before fatal pneumonia. Postmortem examination was notable for RA involving all joints and chronic aortitis. In the same year, Sokoloff and colleagues [4] reported arteritis in small muscular arteries of muscle biopsy tissue in 5 of 57 (10%) adults with RA, the histopathology of which included, mononuclear and polymorphonuclear cell adventitial infiltration, slight necrosis, endothelial cell injury, and secondary elastic involvement without vascular thrombosis or aneurysm formation, and frequent cardiac complication manifesting as pericarditis. The incidence of arteritis is estimated to occur overall in about 8.8% of patients with RA. These observations were followed by 10 additional patient descriptions in 1957 by Sokoloff and Bunim [5] of arteritis in patients with RA. The age range was 30 to 65 years (mean 47 years), at presentation, with a duration of arthritis of 6 months to 30 years (mean 9 years). The diagnosis of RV was established at postmortem examination in five patients and by biopsy of muscle, subcutaneous nodules, and synovial tissue antemortem in five patients. Postmortem examination showed widespread arteritis in three patients, with isolated involvement of the testis in one patient, and the sciatic nerve and coronary artery in another patient. Among the five patients who were diagnosed antemortem, arteritis was detected in muscle biopsy tissue in two patients, in early subcutaneous nodules in two others, and in synovial tissue of another patient. In contrast to the earlier study conducted by the same author of vasculitic muscle biopsy lesions in RA [4], the pathological features of the subsequent 10 patients [5] resembled PAN. Two additional patients with RV were mentioned after publication of the latter study by the same authors [5], both with necrotizing arteritis, in which one was associated with arteritis of the pancreas, and another with isolated peripheral nerve vasculitis (PNV).

TERMINOLOGY AND NOSOLOGY

In 2010, the American College of Rheumatology (ACR), and the European League Against Rheumatism Collaborative Initiative jointly published RA classification criteria [6] that replaced the 1987 Revised ACR criteria for RA [7], defining definite RA by the presence of synovitis in at least one joint, the absence of a better alternative diagnosis, and achievement of a threshold score from the individual scores in four domains in involved joints, in addition to a compatible symptom duration, serological abnormalities, and increased acute-phase responses. This represented a focus upon features associated with earlier disease that was associated with persistent and erosive disease rather than late-stage features thereof. The Revised 2012 Chapel Hill Consensus Conference (CHCC) [8] provides a useful nosology for the vasculitides, categorizing RV as a vasculitis associated with systemic disease. Scott and Bacon [9] described the response to early treatment with intravenous cyclophosphamide and methylprednisolone compared to conventional drug regimens, defining eligible patients as those meeting one or more criteria of the following criteria including, MNM, peripheral gangrene, biopsy evidence of acute necrotizing arteritis plus systemic disease manifested by fever and weight loss; and deep cutaneous ulcers or active ExRA disease if associated with typical digital infarcts or biopsy tissue evidence of vasculitis (Table 1). Overall, the combination of intravenous cyclophosphamide and methylprednisolone resulted in more frequent healing of vasculitic lesions including leg ulcers and neuropathy, and a lower mortality than did other conventional treatments.

Table 1. Scott and Bacon criteria for RV [9]

Mononeuritis multiplex or peripheral neuropathy
Peripheral gangrene
Biopsy evidence of acute necrotizing arteritis plus systemic illness such as fever or weight loss
Deep cutaneous ulcers or active extra-articular disease (pleurisy, pericarditis, scleritis) if associated with typical digital infarcts or biopsy evidence of vasculitis

EPIDEMIOLOGY

In a population-based study of patients living within the Norwich Health Authority in the United Kingdom from 1988 to 1994, the overall annual incidence rate of RV was 12.5 per million (95% CI 8.5 to 17.7) [10]. In a retrospective cohort study of hospitalized RA patients in Malmo, Sweden, from 1990 to 1994, the annual incidence rate of RV was calculated to be 7.1 per million (95% CI 2.7 to 16.1) [11]. This annual incidence rate may underestimate the true incidence rate, as not all patients with RV are hospitalized. There are conflicting data as to whether the incidence of RV has changed or remained stable over recent decades. However, the preponderance of data does suggest that the incidence of RV may in fact be decreasing, perhaps due to improvements in therapy for RA. In an incident RA cohort in Olmsted County, Minnesota, from 1955 to 1994 [12], the 10-year cumulative incidence rate of severe RV, defined as major cutaneous vasculitis and neuropathy due to vasculitis, remained stable by decade of RA diagnosis (2.1% for 1955-1964, 3.5% for 1965-1974, 2.5% for 1975-1984, 4.3% for 1985-1994, p -value = 0.72). However, looking at more recent data

from Olmsted County, Minnesota [13], the 10-year cumulative incidence of RV decreased from 3.6% in the 1985-1994 RA cohort to 0.6% in the 1995-2007 RA cohort on ($p = 0.011$). In a retrospective study of the prevalence of RV among US veterans [14], the prevalence of RV decreased significantly between 2000 and 2001 for both inpatient and outpatient US veterans. The prevalence decreased by 31% (41/1000 RA cases to 28/1000 RA cases, $p < 0.003$) among ambulatory US veterans and by 53% (32/1000 RA cases to 15/1000 RA cases, $p < 0.001$) among hospitalized US veterans. Moreover, an extension of the Norwich Health Authority studies from 1988 to 1994 [10] to 2002 showed a decline in the annual incidence rate of RV over the period 1988 to 2002 [15]. The annual incidence rate of RV in 1988-1992 was 11.6 per million (95% confidence interval [CI] 7.4 to 17.0); in 1993-1997 it was 8.9 per million (95% CI 5.3 to 13.6); and in 1998-2002 it was 3.6 per million (95% CI 1.6 to 7.1) [15]. The overall annual incidence rate of RV during the time period 1988 to 2002 in the former Norwich Health Authority in the UK was 7.9 per million (95% CI 5.9 to 10.4) [15]. Data from a population-based database of hospitalizations in California compiled by the California Office of Statewide Health Planning and Development indicated that the risk of hospitalization for RV was 33% lower in the period 1998 to 2001 than 1983 to 1987 (adjusted rate ratio 0.67, 95% CI 0.61–0.74; $p = \text{value} < 0.0001$). Adjusting for age, sex, and ethnicity, the rate decreased from 170 per 100,000 persons with RA in 1983 to 99 per 100,000 persons with RA in 2001 [16]. A plausible explanation for the declining incidence of RV include more aggressive early therapy and improved therapeutic armamentarium including the use of biologics for treating RA in general. Conversely, there have been rare case reports of vasculitis occurring in the context of therapy with TNF inhibitors, although the magnitude of that complication of anti-TNF therapy in patients with RA is very low [17–21].

Patients who develop RV typically have longer-standing RA lasting 10 years or more [22, 23]. In a retrospective study of 50 patients with RV, the mean duration of RA prior to the onset of RV was 13.6 years [24]. Although RA more frequently affects women than men [22], men are more likely to develop RV than women with RA [10, 23]. In a population-based study of patients living within the Norwich Health Authority in the United Kingdom from 1988 to 1994, the annual incidence rate of RV in men was 15.8 per million (95% CI 9.5 to 24.7) compared to 9.4 per million (95% CI 4.8 to 16.4) in women [10]. Patients with erosive, seropositive disease are also more likely to develop RV than those without destructive disease who are seronegative [23, 25]. Moreover, the presence of certain other extra-articular manifestations of RA, such as rheumatoid nodules and Felty syndrome, has been associated with the development of RV [23, 25, 26]. Smoking is a major risk factor for later development of both RA in general and RV in particular [27–29]. In a case-control study of 45 RA patients with RV and 211 RA patients without RV, a significantly greater percentage of RV patients were current smokers ($p\text{-value} < 0.02$) [28]. In a case-control study of patients with severe RA with and without ExRA from the Mayo Clinic in Rochester, Minnesota, and 3 RA cohorts in Sweden, smoking was an independent predictor of RV in a multivariate mode [29].

An intriguing observation from a large case-controlled study of RV reported from the Mayo clinic suggested that hydroxychloroquine and low dose aspirin use in patients with RA might be protective against the development of RV, perhaps related to the benefits of those interventions with regard to vasculopathy and atherosclerosis [30].

Genetic factors likely also contribute to the development of RV. In a meta-analysis of individual patient data from 1,568 patients with RA, 129 of whom had RV, those with RV

were significantly more likely than others without RV to have a “double dose” of the shared epitope: HLA-DRB1*0401/*0401 (OR 6.2, 95% CI 1.01–37.9), *0401/*0404 (odds ratio [OR] 4.1, 95% CI 1.1–16.2), and *0101/*0401 (OR 4.0, 95% CI 1.4–11.6) [31]. In a case-control study of 46 patients with RV and 178 RA without ExRA from the Mayo Clinic and Sweden, the HLA-C3 allele was positively associated with RV (allele frequency 0.411 in RV patients versus 0.199 in RA controls without ExRA (p-value < 0.001) [29].

CLINICAL PRESENTATION

As mentioned, RV often presents relatively late in the course of the disease and can occur at a time when articular disease activity is not high. Rheumatoid vasculitis can manifest in a variety of ways including, deep cutaneous ulcers [32], digital gangrene [33], nail fold infarcts [34], MNM [35], and scleritis [36, 37]. Systemic vasculitis commonly extends beyond the peripheral nervous system (PNS) and skin, to internal organs including, the stomach, heart, intestine, pancreas, kidney, and gallbladder [22, 38–40]. A postmortem series of 81 Japanese patients with RA showed histologically evident necrotizing arteritis in 25 (30.8%) patients; however, there was no mention of frequency of clinically significant antemortem vasculitic disease. Therefore, the true prevalence of clinically significant arteritis in this cohort might have been significantly less than the 30.8% stated.

Scott and colleagues [24] reported the clinical features of 50 patients with RV based clinically on the development of deep cutaneous ulceration, acute peripheral neuropathy, mononeuritis or MNM; peripheral gangrene or severe systemic disease in the presence of typical digital or nail fold infarcts. So defined, the clinical manifestations of RV in the 50 patients included cutaneous features of digit infarcts, ulcerations, purpura, and gangrene noted in 44 (88%) patients; rheumatoid nodules in 43 (86%); systemic features of weight loss, hepatomegaly and splenomegaly in 41 (82%); sensory or motor neuropathy in 21 (42%); and cardiac involvement. This included pericarditis, arrhythmia, aortic incompetence, and myocardial infarction in 17 (34%); pulmonary involvement including fibrosing alveolitis, pleurisy, effusions and lung nodules in 17 (34%); renal involvement due to amyloid, chronic renal failure, proteinuria and hematuria in 12 (24%); ophthalmic manifestations of scleritis in seven (14%); and gastrointestinal features in five (10%). An open study by Scott and Bacon⁹ of 45 RV patients analyzed treatment with intravenous cyclophosphamide plus methylprednisolone given (21 patients) versus conventional drug regimens including oral azathioprine, prednisolone, D-penicillamine, chlorambucil, oral cyclophosphamide, prostaglandin infusion, and intramuscular methotrexate, in whom the diagnosis of vasculitis was noted in 57% of the former group versus 46% of the latter. In this cohort of severe RV receiving intermittent bolus intravenous cyclophosphamide plus methylprednisolone versus other modalities, rheumatoid nodules were seen respectively in 90% and 71% of patients, nail infarcts in 78% and 70% of cases, neuropathy in 52% and 25%, leg ulcers in 43% and 33%, cardiac involvement in 34% and 18%, peripheral gangrene in 14% and 8%, and ophthalmic manifestations in 14% and 12%. There was more severe initial disease, a higher incidence of neuropathy, and frequent evidence of necrotizing arteritis on biopsy in the former group compared to the latter.

Puéchal and colleagues [41] studied RV among 32 patients defined by the RA and histologically proven necrotizing vasculitis in cutaneous nerve or muscle biopsy tissue specimens respectively in 4 (14%) and 10 (36%) of patients, and together in 14 (50%). The clinical presentation of their patients included 5 (14%) patients with mononeuritis, 18 (51%) patients with MNM, and 12 (34%) patients with distal symmetrical sensory or sensorimotor neuropathy. Cutaneous lesions were seen in 12 (38%) patients including, purpura in nine, ulcers in six, nail-edge infarcts in four, livedo in four, gangrene in two, and one patient each with maculopapular rash or bullous rash. Cardiac involvement was evidenced in four (12.5%) patients including, pericarditis, and fatal rupture of a small mitral valve, congestive heart failure, and myocardial infarction. Eye involvement was noted in two (6%) patients including scleritis and scleromalacia. Life threatening gastrointestinal involvement was noted in 2 (6%) patients due to small bowel perforation and necrosis by endarteritis, accompanied by acute abdomen with sepsis and gangrenous toes and cutaneous ulcers, despite treatment with high-dose corticosteroids and cyclophosphamide therapy,. Altogether, among the 32 patients, all had evidence of PNV that was accompanied by cutaneous vasculitic involvement in 12 patients, 4 of whom had cardiac involvement, and 2 with concomitant vasculitic involvements of nerve, skin, and eye. Four patients had PNV and kidney involvement, and two others had lung involvement.

Vollerstein and colleagues [1] studied 52 patients with RV at the Mayo Clinic from 1974 to 1981 who developed clinical vasculitis evidenced by classic ischemic skin lesions, MNM, or a positive tissue biopsy in comparison to population controls. The initial manifestation of vasculitis was seen in skin in 26 (50%) patients; nerve in 20 (38%) patients, or both in 3 (6%) patients. Serositis, pulmonary or renal manifestations were present each in six patients (12%); and three patients (6%) had eye findings. Mononeuritis presented in 2 (4%) patients; while mononeuritis multiplex involved two nerves in 9 (12%) patients; three nerves in 5 (10%) patients, and four nerves altogether in four (13%) patients. More than 90% of tissue biopsy specimens revealed vascular necrosis and inflammation.

Despite advances in therapy of RA in general, the morbidity and even mortality of RV remains high. A study from the UK reported a mortality rate as high as 60% at 5 years in patients diagnosed with RV despite aggressive therapy usually with cyclophosphamide and high dose corticosteroids. Organ damage and infection were the leading causes of death in this cohort [42].

SEROLOGICAL STUDIES

Among 50 patients with RV described by Scott and colleagues [24], IgM rheumatoid factor (RF) was positive in 94% of patients, the C1q assay was abnormal in 65% of patients, serum antinuclear antibody (ANA) titers were raised in 59% of patients; immune complex assay was positive in 50% of patients overall; with abnormally reduced serum C3 and C4 complement levels respectively in only 0.73% and 0.2% of patients. Serological findings were not mentioned in a report by Scott and Bacon [9] of 45 patients with RV treated with cyclophosphamide and methylprednisolone or other regimens.

In the series of 32 patients with RV described by Puéchal and colleagues [41], in whom vasculitis was obtained in cutaneous nerve or muscle biopsy tissue specimens, articular

erosions were noted in all patients, RF seropositivity was demonstrated in 97% of patients, ANA antibody elevation was noted in 27%, decreased C4 complement titers in 62%, circulating immune complexes in 66%, and cryoglobulins in 13% of patients so studied. At onset of the disease, the erythrocyte sedimentation rate (ESR) was a mean of 80 mm/hour. Hepatitis B surface antigen was not detected in any of the 25 sera so studied, however one patient tested positive for hepatitis B surface antibody; there was no data available for hepatitis C seropositivity.

In the series of 52 patients with RV summarized by Vollerstein and colleagues [1], the ESR was elevated in 44 of 51 (86%) patients; low titers of ANA were noted in 15 of 43 (35%) patients; cryoglobulins in 1 of 28 (4%) patients; immune complexes in 3 of 8 (38%) patients; and C3 and C4 complement was abnormally reduced in 1 of 31 (3%) and 7 of 29 (24%) patients so studied. There is no data on the serological evaluation of the subjects reported by Scott and Bacon [9].

Anti-cyclic citrullinated peptide autoantibodies (anti-CCP) are commonly found at high titers in those with RV, but their absence does not preclude the diagnosis [43]. Anti-neutrophil cytoplasmic antibodies (ANCA) are detectable in greater than a third of patients, generally in a perinuclear (pANCA) pattern. More specific enzyme immunoassays however typically do not reveal the presence of anti-proteinase 3 (PR3) or anti-myeloperoxidase (MPO) antibodies [30, 44].

HISTOPATHOLOGY

RV primarily affects small- and medium-sized vessels [23, 45]. Small-vessel disease may histologically resemble a hypersensitivity vasculitis, whereas medium-vessel disease typically resembles PAN [46]. A given patient with RV may have demonstrable vasculitic involvement of both small- and medium-vessels, with histopathological features of vascular necrosis, occlusion, and tissue ischemia. In a series of 50 patients described by Scott and colleagues [24], vasculitis was noted in 28 patients including leukocytoclastic vasculitis (LCV) of dermal and sub-dermal capillaries was seen in 16 of 19 skin biopsies performed for cutaneous rashes; and necrotizing vasculitis involving small arteries was noted from rectal biopsy tissue in 8 patients, renal biopsy tissue in 2 patients, ovarian and appendix specimens in one patient, and in the coronary artery at postmortem examination in another patient.

Among fifteen patients who died with RV, postmortem examination in seven patients showed active vasculitis in five, three of which showed systemic vasculitis; and one each with vasculitis limited to the coronary arteries, peripheral nerves and muscle, or skin; and inactive vasculitis in another patient. One remaining patient failed to show vasculitis at postmortem examination. In the later series by Scott and Bacon [9], the clinical diagnosis of RV was confirmed histologically in 57% of the patients treated with cyclophosphamide and methylprednisolone compared to 46% of those treated with other conventional therapies. Biopsy tissue specimens of 10 skin rashes showed LCV capillaritis among four patient receiving cyclophosphamide and methylprednisolone, as did six patients receiving other treatments. Deep rectal biopsy showed necrotizing arteritis in nine of 18 (50%), patients who received cyclophosphamide and methylprednisolone compared to four of 17 (24%) patients in the group receiving other treatments.

In the series of 32 patients with RV and PNS, vasculitis described by Puéchal [41], vasculitis was found in nerve biopsy tissue with the same frequency among those with sensory or predominantly sensory neuropathy as among others with predominantly motor findings (67% versus 64%). However, vasculitic nerve lesions were no more frequent in the patients with MNM than those with distal symmetrical sensory or sensorimotor neuropathy (59% versus 78%). Among 44 nerve fascicles from 28 nerve specimens, Wallerian degeneration was noted in three-quarters of fibers compared to segmental demyelination in 1% of fascicles. There was a close correlation between the severity of the clinical neuropathy and degree of axonal loss or fiber degeneration.

Vollerstein and colleagues [1] summarized a series of 52 patients with RV defined by classical ischemic skin lesions including ulceration, gangrene, purpura or petechiae, in the absence of significant atherosclerosis; MNM, or a positive biopsy tissue specimen. Altogether, 26 patients underwent biopsies of skin, nerve or other tissues that showed vascular necrosis and inflammation in more than 90% of specimens. Vasculitis was noted in 17 of 25 (68%) skin biopsy tissues, and in 5 of 25 (25%) nerve biopsy tissues specimens, in addition to one patient each with histologic evidence of vasculitis of the kidney, gastrointestinal tract, and muscle tissues; rectal biopsy tissue specimens were not sampled for vasculitis.

PROGNOSIS

Using actuarial methods and then current ARA criteria for RA [47], Vollerstein and colleagues¹ noted decreased survival of patients with RV when compared to age- and sex-matched Upper Middle Western general population. The clinical factors that predict decreased survival in RV using an univariate proportional-hazards model in older patients includes failure to receive previous non-steroidal anti-inflammatory drug (NSAID) therapy, previous administration of cytotoxic immunosuppressive agents, a higher dosage of corticosteroids at diagnosis, the decision to continue or initiate corticosteroids, and an abnormal urinary sediment ($p < 0.05$). Increasing referral distance, concomitant comorbid disease, hypogammaglobinemia, and hypoalbuminemia also confer a trend toward decreased survival. The authors did not demonstrate a statistically significant association between decreased survival and sex, type of skin lesion, MNM or number of extremities involved, a positive biopsy, initial manifestation of vasculitis, duration of RA, activity of RA, ExRA manifestations or subcutaneous nodules, previous treatment, presence of concentration of RF, C3 and C4 levels, anemia, thrombocytosis, ESR, and abnormal chest radiograph.

Voskuyl and colleagues [48] studied the mortality of 61 RV patients in comparison to 244 RA controls. The unadjusted risk of death (HR) in RV patients compared with RA controls was 1.65 (95% CI 1.05-2.58). After adjustment for prognostic factors, the HR was reduced to 1.26 (95% CI 0.79-2.01), mainly due to removal of the effects of age and sex. There was no excess mortality seen in RV patients with severe organ involvement when compared with RV patients without severe organ involvement, although the former patients were treated more often with cytostatic and immunosuppressive drugs. Infection was the main cause of death in RV patients and cardiovascular disease in the RA controls. Vasculitis was reported as the cause of death in only one RV patient. After allowance for general risk factors

such as age and sex, there remained only a slight excess mortality in RV patients compared with RA controls.

TREATMENT

Isolated nail fold lesions tend to be benign and typically do not require an escalation of immunosuppressive therapy [34].

Cyclophosphamide

Cyclophosphamide in combination with high dose corticosteroids is the mainstay of therapy for RV [49]. An open label study compared intravenous cyclophosphamide plus intravenous methylprednisolone in 21 patients, with a variety of other treating modalities including azathioprine, prednisolone, D-penicillamine, chlorambucil, oral cyclophosphamide, prostaglandin infusion and intramuscular methotrexate in 24 patients, noting that those receiving intravenous cyclophosphamide plus intravenous methylprednisolone were more likely to experience healing or significant improvement in nail infarcts, leg ulcers, sensory neuropathy, and mononeuritis [9]. Patients receiving intravenous cyclophosphamide plus intravenous methylprednisolone were also less likely to have relapses of their RV or to suffer serious complications such as limb amputation or death. Patients receiving intravenous cyclophosphamide plus intravenous methylprednisolone did better than those receiving the other medications despite more serious disease at baseline. In a case series of 16 RA patients with necrotizing scleritis or peripheral ulcerative keratitis refractory to aggressive therapy with topical and systemic steroids and NSAID, 8 (50%) patients ultimately responded to cyclophosphamide, 6 (38%) eventually responded to methotrexate, and 1 (6%) patient eventually responded to cyclosporine A [37]. In addition to medical therapy, 9 (56%) patients with peripheral ulcerative keratitis also required surgical therapy, including ulcer debridement, conjunctival resection, application of cyanoacrylate tissue adhesive, and tarsorrhaphy. Abel and colleagues [50] reported a series of 5 patients with RV who clinically improved following treatment with oral cyclophosphamide. There are patients in whom cyclophosphamide was ineffective and those with contraindications to this particular therapy. In such instances, treatment with other medications, such as tumor necrosis factor (TNF) inhibitors [45, 51] and rituximab [52, 53], has been attempted. However, evidence to date is limited to case reports and case series.

Rituximab

Given its proven efficacy of rituximab in the treatment RA and diverse small vessel vasculitides (SVV) including ANCA associated vasculitis and cryoglobulinemic vasculitis, rituximab is an appealing candidate biologic for the treatment of RV. A retrospective study of 17 patients with RV from the Autoimmunity and Rituximab Registry reported that 12 (71%) patients who achieved a complete response, while 4 (23%) patients showed a partial response

after six months of treatment with rituximab [54]. Twelve months after therapy, 14 (82%) patients achieved sustained complete responses. Hellmann and colleagues [52] report two patients with RV-associated cutaneous ulcers refractory to corticosteroids and disease modifying anti-rheumatic drug therapy but successfully treated with rituximab. Maher and Wilson [53] reported a patient with RV-associated foot drop and sural nerve necrotizing vasculitis in who foot drop improved following multiple courses of rituximab therapy.

Tumor Necrosis Factor Inhibitors

Unger and colleagues [51] reported three patients with RV who developed treatment-limiting adverse effects or a poor clinical response to cyclophosphamide and a later beneficial response to infliximab. Puéchal and colleagues [45] performed a retrospective study of nine patients with RV treated with etanercept or infliximab after failing to respond to treatment with a mean cumulative dose of 8.4 g (range 4 to 15 g) of cyclophosphamide over a mean of 6.2 months (range 3 to 10 months) and high dose corticosteroids. Of the nine patients, 5 developed a complete remission and experienced partial remission after a mean of 28.6 weeks of therapy. Two patients withdrew due to adverse effects and one patient never achieved remission. Two of the patients who responded to TNF inhibitory therapy developed four cutaneous relapses. In 2 patients with RV studied in an open-label pilot study of infliximab [55], both of whom were previously refractory to cyclophosphamide, one demonstrated complete responsiveness to infliximab and another showed a partial response. Garcia-Porrúa and Gonzalez-Gay [56] reported a patient with refractory RV-associated MNM and sural nerve biopsy tissue specimen that revealed necrotizing vasculitis with fibrinoid necrosis in whom foot drop improved after treatment with methotrexate and infliximab. Van der Bijl and colleagues [57] described a patient with RV characterized by fibular mononeuropathy in who foot drop improved following the addition of infliximab to the regimen of methotrexate.

Azathioprine

Azathioprine was evaluated in RV in a small randomized, double blind, placebo-controlled study of 15 patients. No differences between the azathioprine-treated and the placebo-treated groups at a mean duration of 27 weeks of therapy [58] were recognized. In a randomized non-blinded trial in 19 patients with RV limited to cutaneous involvement eight patients were treated with azathioprine and prednisone versus continuation of the existing therapeutic regimen in 11 patients, all taking non-steroidal anti-inflammatory drugs including hydroxychloroquine (one patient), aurothioglucose or gold thioglucose, (two patients) and one each of penicillamine, and one sulfasalazine. Although patients treated with azathioprine and prednisone show greater improvement at 3 months, there appeared to be no significant difference in clinical or laboratory parameters between the two groups at 18 months, [50, 59].

Other Biologics

There are case reports suggesting that tocilizumab, an anti-interleukin (IL)-6 strategy proven effective in giant cell arteritis (GCA), a large vessel vasculitis may be of value in patients with refractory RV [60–62]. Successful treatment of RV with abatacept, a co-stimulatory molecule blocker has been described, and abatacept has been of interest in the treatment of granulomatosis with polyangiitis (GPA), another SVV. Not surprisingly however, given the rarity of the condition and the more common use of cyclophosphamide and now rituximab in patients with severe disease, our understanding of the role of some of these newer biologics in the treatment of RV remains limited.

CONFLICTS OF INTEREST

The Authors have not conflicts of interest to report.

ABSTRACT

Systemic and localized vasculitis affects the skin and subcutis due to their large vascular bed, as well as, hemodynamic factors such as stasis in lower extremities, and environmental influences as occurs in cold exposure. The initial cutaneous manifestations of vasculitides include diverse and dynamic patterns of discoloration, swelling, hemorrhage, and necrosis. One-half of affected patients present with localized, self-limited disease to the skin without any known trigger or associated systemic disease, known as idiopathic cutaneous leukocytoclastic vasculitis. Cutaneous vasculitis manifests as urticaria, erythema, petechiae, purpura, purpuric papules, hemorrhagic vesicles and bullae, nodules, livedo racemosa, deep punched-out ulcers and digital gangrene. Skin biopsy and dermatopathology contribute relevant information however; they require correlation with the clinical history, physical exam and laboratory findings in order to reach an accurate diagnosis in a given affected patient.

INTRODUCTION

Systemic and localized vasculitis affects the skin and subcutis due to their large vascular bed, as well as hemodynamic factors such as stasis in lower extremities, and environmental influences as occurs in cold exposure. The initial cutaneous manifestations of vasculitides include diverse and dynamic patterns of discoloration, swelling, hemorrhage, and necrosis. One-half of affected patients present with localized, self-limited disease to the skin without any trigger or associated systemic disease, known as idiopathic cutaneous leukocytoclastic vasculitis (LCV) [1]. Cutaneous vasculitis manifests as urticaria, erythema, petechiae, purpura, purpuric papules, hemorrhagic vesicles and bullae, nodules, livedo racemosa, deep punched-out ulcers and digital gangrene [2]. Skin biopsy and dermatopathology contribute relevant information however; they require correlation with the clinical history, physical exam and laboratory findings in order to reach an accurate diagnosis in a given affected patient. The vasculitides that present primarily and within their course with cutaneous manifestations are summarized in Table 1. This chapter is a comprehensive overview of the clinical dermatologic aspects of primary and secondary vasculitides.

GENERAL CONCEPTS AND NOSOLOGY

The skin receives its blood supply from penetrating vessels from within the underlying subcutaneous fat, which contains medium sized vessels [3]. Branches of medium-sized vessels give rise to two vascular plexuses that intercommunicate, the deep vascular plexus lying at the interface between the dermis and subcutaneous fat, and the superficial plexus located in the superficial aspects of the reticular dermis. Further, distally, they supply the papillary dermis by forming capillary loops. These loops are composed of terminal arteriole, capillaries (arterial and venous), and post-capillary venules (Figure 1). The type of cutaneous lesions closely correlates with the size of vessel affected by vasculitis. For example, in cutaneous LCV, immune complexes (IC) deposition and inflammation mainly target post-capillary venules giving rise to small palpable purpura (Figure 2). Inflammation that targets arterioles and arteries results in large purpuric lesions with irregular borders (Figure 3) since these vessels supply multiple dermal papillae. Ulcers, nodules, pitted scars, and livedo reticularis are associated with arterial muscular vessel involvement, which is localized to the dermal-subcutis interface or within the subcutis [4]. Table 2 reviews the size of vessel affected with corresponding clinical presentation. The 2012 Revised Chapel Hill Consensus Conference (CHCC) [5] and most recent dermatological addendum for the 2012 CHCC [6] serves as a guide for the nosology and categorization of diverse forms of vasculitis based upon the vessels involved. The Pediatric Rheumatology European Society (PRES) and the European League against Rheumatism (EULAR) and the Pediatric Rheumatology International Trials Organization (PRINTO) proposed nosology and classification for several of the primary pediatric vasculitides based upon vessel size [7, 8] similar to the CHCC nomenclature [5]. The clinicopathological aspects of primary and secondary vasculitides are extensively reviewed in Chapter 2 of this text.

Table 1. Percentage of patients with systemic vasculitis presenting primarily and within their course of disease with cutaneous manifestations

Type of Vasculitis	Cutaneous manifestation as first clinical presentation	Cutaneous manifestations during their course of disease	Most common cutaneous manifestation
Microscopic polyangiitis	4 - 14%	44 - 62.4%	Purpura
Granulomatosis with polyangiitis	< 1-21%	10 - 40%	Purpura
Eosinophilic granulomatosis with polyangiitis	14%	40 - 81%	Purpura
Polyarteritis nodosa	11%	25 - 60%	Purpura
Connective tissue diseases	-	12%	Purpura*
Giant cell arteritis	< 1%	-	Scalp tenderness/blanching
Levamisole-induced vasculitis	-	60%	Purpura involving the ears
Henoch-Schönlein Purpura	-	100%	Purpura
Cryoglobulinemic vasculitis	-	100%	Purpura

* Except for Lupus Vasculitis which most commonly presents as erythematous punctate lesions of the fingertips.

Figure 1. The size of vessel involvement is one histologic feature coupled with the predominant inflammatory cell that allow for classification of most common forms of cutaneous vasculitis. In general, HSP/IgAV cutaneous leukocytoclastic vasculitis affects superficial skin vessels whereas polyarteritis nodosa, nodular vasculitis and giant cell arteritis affect deep muscular vessels found at the dermal-subcutis interface and within the subcutis. Most other forms of vasculitis such as cryoglobulinemic vasculitis and ANCA-associated vasculitis that affect multiple visceral organs more diffusely affect the vascular tree. The depth and type of skin biopsy greatly influences the diagnostic yield.

Figure 2. Typical palpable purpura, some with central necrosis in a patient with idiopathic cutaneous vasculitis of the legs.

Figure 3. Large purpuric lesions with irregular borders affecting the left wrist of a patient with idiopathic systemic vasculitis.

Table 2. Clinical manifestations of vasculitis based on vessel size affected

Large vessel	Medium vessel	Small vessel
Limb claudication	Subcutaneous nodules Nodular erythema	Purpura, infiltrated/elevated erythema
Asymmetric blood pressure	Ulcers	Urticaria
Absence of pulses	Livedo reticularis	Vesiculobullous lesions
Aortic dilation	Pitted palmar/digital scars	Splinter Hemorrhages
Bruits	Digital Gangrene	Scleritis, episcleritis, uveitis
	Mononeuritis	Palisaded neutrophilic granulomatous dermatitis*
	Aneurysms	Glomerulonephritis
	Infarct	Gastric colic
	Hypertension (renal artery)	Pulmonary hemorrhage

Constitutional symptoms: fever, weight loss, malaise, arthralgias and arthritis are common to vasculitic syndromes of all vessel sizes

* Extravascular necrotizing granuloma. Small vessel neutrophilic vasculitis is frequently seen in the vicinity of granulomas and necrosis

Table adapted from Carlson et al. [15].

EPIDEMIOLOGY

The incidence of cutaneous vasculitis ranges from 15.4 to 29.7 cases per million per year, affecting adults more than children of all ages, with slight female predominance, and up to 90% of children diagnosed with Henoch–Schönlein purpura (HSP/ IgA vasculitis [IgAV]) [1]. The mean age at presentation of adult vasculitis is 47 years, while amongst children the mean age at onset is 7 years [1, 4]. The onset of vasculitis after exposure to a trigger such as a drug or infection is 7 to 10 days. A mean interval of 6 months occurs between the onset of symptoms and signs of systemic disease and the onset of secondary cutaneous vasculitis. Almost one-half of patients presenting with cutaneous vasculitis have disease localized to the skin without an attributable cause, trigger or associated systemic disease, referred to as idiopathic LCV [1]. The remainder of localized cutaneous vasculitis cases are attributed to recent infection and drug ingestion. LCV that results from drugs or infection is termed hypersensitivity or allergic vasculitis. The antinuclear cytoplasmic antibody (ANCA)-associated vasculitides (AAV) vasculitis syndromes include eosinophilic granulomatosis with polyangiitis (EGPA) (previously known as Churg-Strauss Syndrome [CSS]), microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) (previously known as Wegner granulomatosis [WG]) may first present with cutaneous vasculitis [9]. The onset of cutaneous vasculitis may be an indication of secondary vasculitis in association with connective tissue disease (CTD) such as systemic lupus erythematosus (SLE) vasculitis (LV) [10], and rheumatoid arthritis (RA) related vasculitis (RAV) [11].

The evolution of cutaneous vasculitis occurs in three phases, (a) single acute, self-limited episode that resolve in ≤ 6 months in association with drug exposure or an infectious trigger so noted in 60% of patients; (b) relapsing disease with symptom-free periods usually found in patients with HSP/IgAV and cryoglobulinemic vasculitis (CV) so noted in 20% of patients; and (c) a chronic, unremitting disease most often associated with primary systemic vasculitides and secondary vasculitides in association with CTD, CV, or malignancy altogether in about 20% of patients [1]. The duration of vasculitis ranges from 1 week to 318 months, with mean and median durations of 28 months and 3.7 months, respectively. Less than 20% of cutaneous vasculitis cases have extracutaneous or visceral vasculitis. Fatal disease occurs in less than 7% of patients [1, 12].

ETIOPATHOGENESIS

A variety of injurious processes can lead to identical responses in the vessel wall resulting in the activation of neutrophils, abnormal neutrophil diapedesis and fibrinoid necrosis, the hallmarks of the vasculitides [1, 13]. Other morphological patterns of vasculitis include lymphocytic endarteritis and endarteritis obliterans of transplant vascular rejection, which are not generally associated with abundant fibrin deposits and destruction of the vessel wall with loss of the elastic lamina [14, 15]. Adding to the difficulties in the histological evaluation of vasculitides are that the characteristics of the initial insult may be lost during the process of repair leading to the transformation from active, acute inflammatory lesions into older, often sclerotic lesions wherein T-cells and macrophages predominate and neovascularization transpire to compensate for the ischemic insult. Nonetheless, the type of

inflammatory cell mediating vessel damage and vessel size affected roughly correlates with pathogenic mechanisms. Ascertaining the optimal time for obtaining the skin biopsy offers relevant preserved data of the skin lesion. An estimated time of a lesion within 24 to 48 hours of its onset is ideal for the biopsy, and for immunofluorescence between 8 to 24 hours [16].

CLINICAL PRESENTATION

Systemic symptoms of fever, malaise, weight loss, arthritis, and arthralgia accompany most cutaneous vasculitides. Vasculitic lesions may affect dependent sites of the legs especially under tight fitting clothes, less so along the arms, trunk, head and neck signifying more severe disease or coexisting systemic vasculitis [17]. Cutaneous vasculitis commonly manifests as palpable purpura and infiltrated erythema indicating dermal small vessel vasculitis (SVV), less frequently as nodular erythema, livedo racemosa, punched-out ulcers, or digital gangrene due to muscular-vessel vasculitis. The type of cutaneous lesions closely correlates with the size of vessel affected by vasculitis. Sparse superficial perivascular neutrophilic infiltrates associated with nuclear debris and extravasated red blood cells result in urticarial papules and plaques, which last > 24 h, burn rather than itch, and resolve with residual pigmentation (Figure 4). A predominant small vessel vasculitis (SVV) results in purpuric macules and infiltrated erythema, whereas deeper dermal SVV correlate with palpable purpura and vesiculobullous lesions. Ulcers, nodules, pitted scars, or livedo reticularis are associated with arterial muscular vessel involvement, which will be located at the dermal–subcutis interface or within the subcutis [4].

Figure 4. Urticarial vasculitis (UV): patient with hypocomplementemia presenting with an urticarial rash that lasts for more than 24 hours in fixed locations which subsequently slowly resolves spontaneously. They can possibly resolve leaving ecchymosis and hyperpigmentation. Histologically, the features (as in most cases of UV) show perivascular neutrophilic infiltrate with red blood cell extravasation but no fibrin deposition.

LABORATORY EVALUATION

Histopathologic Studies

Table 3 shows the histologic criteria for the diagnosis of cutaneous vasculitis. The diagnosis of cutaneous vasculitis of small- and medium-sized muscular vessels is established by biopsy and examination of hematoxylin and eosin (H& E)-stained sections followed by direct immunofluorescent (DIF) studies. Fibrinoid necrosis is comprised of fibrin deposition within and around the vessel wall and is a feature of nearly all early vasculitic lesions. It results from the accumulation of plasma proteins, including coagulation factors that are converted to fibrin along sites of vessel wall destruction. Inflammatory infiltrates within and around the walls of vessels accompanied by fibrin deposition (Figure 5) may be accompanied by endothelial damage in the form of endothelial swelling and shrinkage due to apoptosis and sloughing (Figure 6). The finding of inflammatory cells infiltrating the adventitia and media and disrupting the endothelium or endothelialitis, is a *de facto* sign of vasculitis (Figure 7). Secondary changes that infer underlying vasculitis include extravasation of red blood cells causing purpura, necrosis leading to infarction, and ulceration secondary to the ischemia and vessel obstruction. The type of inflammatory cells mediating vessel damage and the caliber of the vessels affected roughly correlate with pathogenic mechanisms listed in Table 4. Circumstantial evidence of vessel wall damage includes lamination of the adventitia, media and/or intima of vessels or so-called onion skinning (Figure 8); perivascular nuclear dust or leukocytoclasia (Figure 9) without fibrin deposits such as in early evolving LCV; sharply defined loss of the elastic lamina associated with acellular scar tissue in the healed stage of muscular vessel vasculitis; and sub endothelial, intramuscular, and adventitial inflammatory cells. Neovascularization of the adventitia (Figure 10) and the formation of small capillaries are prominent features of mature and older lesions in chronic localized SVV such as erythema elevatum diutinum, medium vessel vasculitides (MVV) such as polyarteritis nodosa (PAN), and large vessel vasculitides (LVV) such as giant cell arteritis (GCA), Luminal obliteration or endarteritis obliterans, the ischemic consequence of lymphocytic and granulomatous vasculitides, affects small- to medium-sized arteries. Endarteritis obliterans occur in several stages. First, lymphocytic endothelialitis or endarteritis is followed by formation of a sponge-like plug composed of mononuclear cells, fibrin, and red blood cells resulting in partial to complete obstruction. Perivascular lymphohistiocytic, non-neutrophilic, inflammatory infiltrates develop around affected arteries, followed by formation of dilated capillaries in the adventitia of obstructed vessels. Smooth muscle cells immigrate and proliferate in the subendothelial zone, organizing the occluding plug during the intermediate stage. The final stage is fibrosis, shrinkage, and atrophy of the occluded artery (Figure 11). Healed lesions may be associated with luminal stenosis and aneurysm formation. Persistence of vessel wall inflammation, either medial or intimal, can eventually lead to luminal obliteration or aneurysm rupture.

Immunofluorescence analysis of a tissue biopsy of involved skin lesions is indispensable. The commonest immunoreaction found in vessels by DIF is C3, followed by IgM, IgA and IgG, and fibrin deposits [1, 4]. The type of Ig and pattern of deposits in DIF will be of additional diagnostic value. For example, predominance of IgA in HSP/IgAV (Figure 12) will direct attention to renal involvement. Basement membrane zone or keratinocyte nuclear or *in*

vivo ANA and IgG immunoreactions are found in vasculitides associated with CTD such as LV. The finding of basement membrane zone immunoreactions occurs in those with HUV/C1q and CTD. In addition, IgM deposition in blood vessels, circulating RF and monoclonal production of IgM are readily seen in patients with CV and RAV.

Table 3. Histologic diagnostic criteria for cutaneous vasculitis and associated histology¹

Histologic signs of acute (active) vasculitis
<i>Dermal small vessels (venules and arterioles) (2 of 3* criteria needed)</i>
*Angiocentric(†) and/or angio-invasive inflammatory infiltrates
*Disruption and/or destruction of vessel wall by inflammatory infiltrate
*Intramural and/or intraluminal fibrin deposition (“fibrinoid necrosis”)
<i>Dermal-Subcutaneous muscular vessels (small arteries and veins)</i>
*Infiltration of muscular vessel wall by inflammatory cells
*Intramural and/or intraluminal fibrin deposition (“fibrinoid necrosis”) [§]
<i>†Secondary changes of active vasculitis (suggestive of, but not diagnostic of vasculitis)</i>
RBC extravasation (petechiae, purpura, hematoma)
Nuclear dust, perivascular (leukocytoclasia)
Endothelial swelling, sloughing or necrosis
Eccrine gland necrosis (or regeneration with basal cell hyperplasia)
Ulceration
Necrosis/infarction
Histologic sequelae of vasculitis (chronic signs and healed lesions of vasculitis)
†Lamination (onion-skinning) of vessel wall constituents
†Luminal obliteration (endarteritis obliterans)
*Segmental or complete loss of elastic lamina in medium and large vessels associated with acellular scar tissue
†Reactive angioendotheliomatosis
Neo-vascularization of adventitia

*: Required for diagnosis of vasculitis.

[§]: Intraluminal fibrin deposition can be found in non-vasculitic arterial lesions such as malignant hypertension and anti-phospholipid antibody syndrome.

†: Other types of vessel injury (pseudovasculitis [91]) can cause same pattern

Figure 5. Inflammatory infiltrates within and around the walls of vessels accompanied by fibrin deposition indicative of vasculitis.

Figure 6. Endothelial swelling, shrinkage, apoptosis, and sloughing seen in early and mature lesions of urticarial vasculitis occurring in association with hepatitis C virus infection.

Further laboratory evaluation of patients with cutaneous vasculitis should be guided by the history and physical examination as to the possibility of preexisting or concomitant systemic illness, including relevant drug and infectious exposures [1, 18]. Clues to the presence of underlying systemic illness include night sweats, weight loss, dry eyes and mucous membranes, photosensitivity, facial cutaneous eruption, oral lesions, muscle weakness, mononeuritis multiplex, arthralgia, myalgia, fever, hemoptysis, shortness of breath, cough, wheezing, eye or ear symptoms, sinusitis, hoarseness, numbness or paresthesia, abdominal or testicular pain, melena, and hematuria [1, 18]. Patients with suspected of a primary vasculitides should undergo baseline complete blood cell count (CBC) with differential, blood

urea nitrogen (BUN), creatinine, liver function panel, urinalysis, stool guaiac, hepatitis B (HBV) and C virus (HCV) serology, antinuclear antibody (ANA), cryoglobulins, and ANCA testing. Other studies include blood cultures and echocardiography when fever or heart murmurs are present, anti-streptolysin O titers in children and adults with a history of cardiac septal defect; cytokines IL-6, TNF α , C-reactive protein (CRP), activated coagulation marker complex thrombin–antithrombin III, functional endothelial markers endothelial microparticles and thrombomodulin; and ANCA serology when SVV (MPA, EGPA, GPA) is suspected. Perinuclear pattern of ANCA (pANCA) with myeloperoxidase (MPO) antibodies as well as lactoferrin and cathepsin, which occurs most often in MPA and EGPA. Cytoplasmic (cANCA) with proteinase-3 (PR3) is strongly associated with GPA.

Figure 7. Lymphocytes infiltrate the adventitia and media of a small vein and the intima shows extensive fibrin deposits.

Figure 8. Erythema elevatum diutinum- chronic localized fibrosing leukocytoclastic vasculitis. Concentric rings of collagen surround this small vessel due to recurrent leukocytoclastic vasculitis. There is a cycle of vasculitis → vessel damage → and granulation tissue formation.

Figure 9. Deposition of neutrophilic nuclear debris or leukocytoclasia. Note the disruption of the small thin wall vessel by fibrin and numerous degenerated adventitial apoptotic neutrophilic nuclei.

Figure 10. Neovascularization in cutaneous polyarteritis nodosa. CD31 staining marks the vasculature and as demonstrated in this image, reveals multiple newly formed vessels surrounding the affected vessel.

The presence of ANCA is not diagnostic of systemic vasculitis since up to 60% of patients with cutaneous LCV can be ANCA-positive with disease limited to the skin. Positive ANCA serology so noted in diverse systemic inflammatory and pulmonary disorders that mimic vasculitis [19] usually demonstrates atypical indirect immunofluorescent patterns with negative antibodies to PR-3 and MPO by antigen specific enzyme-linked immunosorbent assays (ELISA). The absence of IC and the presence of minimal IgG and C3, so-called pauci-immune vasculitis, are expected findings in GPA, EGPA and MPA. These three vasculitides can present with negative serology and exploring other antigen targets for such situations may

be of diagnostic utility. Kain and colleagues found the serum anti-human lysosomal-associated membrane protein-2 (hLAMP-2) to be positive in different assays in > 80% of untreated 122 AVV patients. Levels dropped to almost becoming undetectable once the immunosuppression therapy started, raising the possibility to be used as a biomarker and contrasting with MPO and PR3 antibodies, which do not correlate well with the disease activity due to different kinetics. Moreover, in the same study, positive anti-hLAMP-2 antibodies were found in 7 out of 8 ANCA, PR3 and MPO negative patients [20]. Inadequacies of current assay techniques limit hLAMP-2 antibody kits to be commercially available; even they have shown to have a high sensitivity and clinical correlation, but poor specificity for cutaneous AAV, as they were also detected in HSP and cutaneous polyarteritis nodosa [21].

Patients with suspected secondary vasculitis and biopsy-proven cutaneous vasculitis in association with a serologically specific CTD, so suggested by dry eyes and mouth, arthritis, sclerosis, or photosensitivity, should be further screened for antinuclear antibody (ANA), rheumatoid factor (RF), anti-phospholipid (aPL), Ro (SSA), La (SSB), ribonucleoprotein (RNP) and Sm (Smith) antibodies [1, 22, 23]. The secondary vasculitides in association with CTD typically involve multiple organs and vessels of variable caliber. Extravascular histologic findings can provide a clue to diagnosis of associated CTD. Examples include interface dermatitis with dermal mucin deposition so noted in SLE and dermatomyositis; dermal or subcutaneous sclerosis in scleroderma; as well as, palisading neutrophilic and granulomatous dermatitis in RA and SLE, and tissue neutrophilia, rather than a neutrophilic dermatosis, in SLE and Sjögren syndrome [2].

Figure 11. The four morphologic stages of cutaneous polyarteritis nodosa with end-stage healed arteritis or endarteritis nodosa. The acute stage is characterized by endothelial loss and fibrin thrombi with neutrophil infiltration without obvious internal elastic lamina disruption and medial fibrinoid necrosis. The subacute stage shows mixed cellular infiltration and unique intimal target-like fibrinoid necrosis and leakage extending through the disrupted internal elastic lamina sites to the media. The reparative stage shows intimal fibroblastic proliferation and perivascular neovascularization with predominant histiocyte and lymphocyte infiltration. The healed stage reveals minimal cellular inflammation and occlusive intimal thickening.

Figure 12. Petechial leg eruption in HSP/IgAV. Skin biopsy shows neutrophilic small vessel vasculitis restricted to the superficial dermis. Direct immunofluorescence demonstrates IgA vascular deposits.

PRIMARY SMALL VESSEL VASCULITIDES

ANCA-Associated Vasculitides

Microscopic Polyangiitis

This neutrophilic necrotizing SVV characteristically involves arterioles, capillaries, and venules, and occasionally small and medium arteries of the kidney and lung resulting in pulmonary capillaritis and necrotizing glomerulonephritis. It typically affects patients > 50 years of age, with a male: female ratio of 1:1.5, and a greater prevalence in Asians [24]. The largest cohorts ascertained in departments of medicine or nephrology render a bias toward certain spectrums of the disease [25] and may underestimate the true incidence of cutaneous manifestations [26]. Agard and coworkers [27] found skin lesions, primarily purpura, at presentation in 14% of 36 patients, compared to 4% by Cupps and Fauci [28]. Kluger and colleagues [29] ascertained skin manifestation in 44% of 162 patients comprised of palpable purpura of the legs in 26%, livedo racemosa in 12%, nodular lesions in 10%, ulcer/necrosis in 6%, urticaria in 1.2%, oral and genital ulcers each in 0.6%; arthralgia, mononeuritis multiplex and ocular symptoms occurred more often as well. Guillevin and coworkers [30] observed cutaneous involvement, primarily purpura, in 62.4% of 85 patients.

The French Vasculitis Study Group (FVSG) [31], a multicenter nationwide study, that retrospectively analyzed 1553 AAV patients, noted cutaneous manifestations (CM) overall in 51.9%, typically at a younger age (57.5 years) with features of segmentary edema (19.5%) and livedo reticularis (12.4%), as compared to those with GPA and EGPA. In addition, myalgia, arthralgia, gastrointestinal hemorrhage and peripheral neuropathy were all

significantly more frequently in association with CM, with less frequently impaired renal function [31].

Figure 13. Granulomatosis with polyangiitis. This young 22-year old female presented with progressive ocular (episcleritis), ear, and lung symptoms and history of tuberculosis. Chest radiograph showed left lung nodule cavitation. Cutaneous exam revealed painful papules some of which were vesicular over the volar aspects of the proximal phalanges. Punch biopsy was diagnostic of granulomatosis with polyangiitis.

Figure 14. Punch biopsy of the patient in Figure 13 that shows regional epidermal necrosis overlying a pandermal infiltrate characterized by neutrophilic small vessel vasculitis (bottom left panel), and surrounding, palisading granulomatous inflammation associated with basophilic debris or blue collagenolytic granuloma.

Granulomatosis with Polyangiitis

The clinicopathological features of GPA include granulomatous inflammation of the upper and lower respiratory tracts (Figures 13, 14) and necrotizing granulomatous inflammation of the kidneys leading to glomerulonephritis [23]. The disease is not evenly distributed among geographic areas, time intervals or ethnic populations [32]. The diagnosis rests upon a positive biopsy demonstrating surrogate markers of granulomatous inflammation of the respiratory tract and kidney and the presence of systemic necrotizing vasculitis of small-to medium-sized vessels, and positive c-ANCA specifically targeting intra-granular, anti-proteinase-3 (PR3), but without blood or biopsy tissue eosinophilia. About 10% to 50% of patients with GPA develop cutaneous disease during the course of disease [33-36] that takes one of many forms including, palpable and non-palpable purpura due to small vessel neutrophilic vasculitis; subcutaneous nodules, ulcers and digital infarcts with gangrene due to medium vessel vasculitis (Figure 15). Polymorphic lesions consist of necrotic rheumatoid papules and nodules along extensor surfaces particularly the elbows; and pyoderma gangrenosum-like ulcers and gingival hyperplasia with strawberry gingivitis.

Figure 15. Digital gangrene in a patient with muscular-vessel vasculitis and radial artery thrombosis, status post thrombectomy. The patient was diagnosed subsequently as granulomatosis with polyangiitis.

Among 40 patients with the diagnosis of GPA described by Patten and colleagues [33], 16 (40%) had cutaneous and oral mucosal disease, 12 of whom had a skin alone, most commonly palpable purpura; and 2 each had oral mucosal disease or both skin and mucosal disease leading to oral ulcers, with a single example of gingival hyperplasia. Among 766 ANCA-positive patients with GPA, Comfere and colleagues [34] noted skin manifestations in about 10% of patients, several of whom underwent skin biopsy evidencing concomitant cutaneous and systemic involvement, isolated cutaneous disease several weeks to 8 years after diagnosis of systemic GPA, and others in whom the cutaneous eruptions preceded systemic involvement by one to seven years. Among 66 patients with GPA Zycinska and coworkers [35] discerned skin involvement in 21 (32%) patients, 14 (21%) of whom had skin involvement as an initial clinical presentation. The histologic identification of isolated LCV,

cutaneous GPA, and positive c-ANCA/PR3-ANCA serologic test results should raise clinical suspicion for later systemic involvement.

In the AAV cohort of the FVSG, CM noted in 36.7% of cases, manifested frequent oral ulceration (4.6%) and two distinctive lesions: pyoderma gangrenosum (1.1%) and gingival hyperplasia (0.9%). There was frequent alveolar hemorrhage, arthralgia, peripheral neuropathy, renal, cardiovascular and gastrointestinal involvement. Patient with GPA and CM had more frequent vasculitis than the granulomatous phenotype and poorer relapse-free and overall survival. Patients with GPA and predominant granulomatous features manifesting lung nodules and pachymeningitis had infrequent CM [31]. The histopathology of GPA is a LCV with fibrinoid necrosis mostly affecting small vessels and preferentially the dermis. Fewer cases show deeper tissue inflammation. Other presentations include purpura, nodules, papules, urticaria and granulomatous vasculitis. Neutrophils prevailed in almost all the specimens. Among 52 pediatric GPA cases [37], CM noted in 36.5% of cases, was a presenting feature in 7.7%. Nineteen patients had specific findings related to the disease presenting as palpable purpura, folliculitis, pyoderma gangrenosum-like and nodules, with histopathologic findings of leukocytoclastic vasculitis, granulomatous inflammation, granulomatous vasculitis and palisading granulomas. Acneiform papules and pustules with perifollicular inflammation are unique to this age group [37].

Eosinophilic-Granulomatosis with Polyangiitis

Patients with EGPA present clinically with adult-onset of asthma and allergic rhinitis, and pathologically with necrotizing granulomatous inflammation, peripheral blood and tissue eosinophilia, and systemic vasculitis [23] in adults age 30 to 60 years without gender differences [38]. There is frequent renal disease and more frequent peripheral nerve, cutaneous, and cardiac involvement compared to GPA. ANCA-positive patients are more likely to have cutaneous vasculitis, alveolar hemorrhage, mononeuritis multiplex and renal disease [39]. In contrast to GPA and MPA, 40% of EGPA cases are ANCA-positive, with most manifesting p-ANCA and MPO specificity (in 30% - 40%) [40], and fewer cases presenting with c-ANCA and PR3 seropositivity. Following a prodromic initial phase of asthma and allergic rhinosinusitis, a second phase ensues with peripheral blood and tissue eosinophilia demonstrable in the lungs, heart and other organs; followed by a third phase of frank vasculitis. Cutaneous manifestations were the presenting feature of EGPA patients in about 14% of cases [41], so noted in 40% to 80% of cases [42].

The lesions of EGPA were first described in 1951 as erythematous maculopapular lesions resembling erythema multiforme; also include petechiae, palpable purpura, urticarial papules; and cutaneous and subcutaneous nodules [43]. In a recent cohort, the skin manifestations of EGPA at initial onset included palpable purpura, petechiae, ecchymosis and hemorrhagic bullae in $\leq 50\%$ of patients; dermal and subcutaneous papules and nodules on the scalp or symmetrically distributed over the extremities (Figure 16) in about 30%; and urticaria and erythematous macules in $\leq 25\%$ of patients, with others manifesting livedo reticularis. In the FVSG cohort, among 436 EGPA cases, 53% presented with CM along with more frequent fever (50.9%), arthralgia (44.1%), ocular involvement (12.5%), alveolar hemorrhage (7.8%) and gastrointestinal involvement (29.5%), without cardiovascular, neurological or renal involvement [31].

Figure 16. Dermal and subcutaneous papules around the elbows and hemorrhagic bullous purpuric macules and papules over the lower extremities in a patient with eosinophilic granulomatosis with polyangiitis.

Figure 17. Eosinophilic arteritis with thrombophlebitis in a patient with eosinophilic granulomatosis with polyangiitis.

Cutaneous biopsy reveals three histopathologic changes, alone or together, including 1) eosinophil-rich neutrophilic SVV affecting dermal venules and arterioles, less commonly an eosinophil-rich muscular arteritis (Figure 17) or granulomatous histiocyte-rich arteritis of the dermal subcutaneous junction or subcutis; dermal eosinophilia; 2) palisading neutrophilic and granulomatous dermatitis with neutrophilic debris among basophilic degenerated collagen bundles, so called blue granuloma (Figure 14) or abundant eosinophils and eosinophilic granules and debris that coat degenerated collagen bundles or red granulomas (Figure 18) [23, 44, 45]; and less often, 3) granulomatous arteritis [45].

Immune Complex Vasculitides

Henoch Schönlein Purpura/IgAV

Comprising about 10% of all cases of cutaneous vasculitis and about 90% cases of primary childhood vasculitis [1, 23], HSP/IgAV is characterized by retiform or patterned purpura preceded by an upper respiratory tract infection in about one-half of children and a recent drug exposure in a minority. Isolated or predominate IgA vascular deposits, and two or more of the following support the diagnosis: age ≤ 20 years, colicky gastrointestinal pain or hematochezia, an upper respiratory tract infection prodrome, hematuria, and renal biopsy showing mesangioproliferative glomerulonephritis with or without IgA deposits. Renal disease is found in HSP patients with a history of recent infection, fever, lesions above the waist or spread of purpura to the trunk, and papillary dermal edema and perivascular C3 on DIF histopathology [46, 47]. Long term follow-up is necessary in children with abnormal baseline urinalysis [48] since up to 20% develop chronic renal failure compared to those with a normal baseline urinalysis in which no person developed later renal impairment [48, 49]. Patients with fever, purpura above the waist, and elevated erythrocyte sedimentation (ESR) rate are more likely to develop IgA glomerulonephritis. In addition, in the pediatric population, serum pentraxin3 levels predicts future renal disease [50]. Furthermore, the lesions above the waist and edema on the exam are associated with gastrointestinal involvement [47]. Skin biopsy in patients with HSP/IgAV demonstrates neutrophilic SVV restricted to the superficial dermis (Figure 12), although the whole dermis may eventually become involved [51]. Patients older than age 40 years with HSP/IgAV with absent eosinophils on histologic examination of skin tissue had a three-fold increased risk of renal involvement compared to those younger than age 40 with tissue eosinophilia [52]. The IgA and IgM deposits in the skin by DIF also predicts renal disease [50].

The link of HSP and familial Mediterranean fever (FMF) has been well known since recognition that the classical features of the former, including purpura, gastrointestinal tract bleeding hematuria, localized edema, arthritis and positive skin biopsies; overlapped with periodic fever and abdominal pain lasting for 1 to 3 days, of the latter [53]. Pathophysiological inflammatory mechanism include complement consumption and circulating immune complexes [54]. Features unique to HSP include the absence of classical cutaneous IgA deposits on DIF, and recurrent, dispersed purpuric lesions of atypical areas along the face and trunk [54]. Serum anti-LAMP-2 antibodies were significantly higher in 36 HSP patients versus 51 healthy controls [55].

Cryoglobulinemic Vasculitis

Cryoglobulins are cold-precipitating immunoglobulins that persist in the serum and solubilize when rewarmed. There are three types, type I, monoclonal cryoglobulins that comprise 10% to 15% of all cases and produce non-inflammatory small vessel hyaline thrombi; type II or mixed monoclonal IgM with RF activity and polyclonal IgG cryoglobulins which comprise 50% to 60% of cases; and type III or mixed polyclonal IgM with RF activity and IgG cryoglobulins comprising 30% to 40% of cases. The oligoclonal type consists in the composite of oligoclonal IgM (several monoclonal) against polyclonal IgGs with RF activity and is described as a transitional form type or IIa, [56]. Type II and III mixed cryoglobulinemia are associated with CTD, hematologic malignancies and HCV infection.

Greater than 50% of HCV-seropositive patients have mixed cryoglobulins, and a lesser frequency of vasculitis. Persistence of CV immunological features was reported in 52% of effectively treated patients with HCV after 12 weeks of anti-viral therapy who potentially may remain clinically active [57].

Figure 18. Multiple red collagen lytic granulomas in a patient with eosinophilic granulomatosis with polyangiitis.

Reproduced courtesy of Henry Foong, MD, Ipoh, Malaysia).

Figure 19. Severe cutaneous polyarteritis nodosa with secondary livedoid vasculopathy.

Cryoglobulinemic vasculitis is characterized by Meltzer's clinical triad of purpura triggered by cold exposure or prolonged standing, arthralgia, and weakness in association with mixed cryoglobulinemia. Other cutaneous manifestations include PAN-like lesions,

ulcers, splinter hemorrhages, palmar erythema and even digital gangrene if digital vessels become obliterated, this later, especially whenever the cryocrit is elevated. Systemic disease in CV includes glomerulonephritis, neuropathy, and pulmonary involvement with high titers of RF and low levels of C4. Most patients demonstrate neutrophilic SVV that equally affects vessels of the superficial dermis and subcutis on skin biopsy with vascular IgM and complement deposits on DIF; a minority of patients displays PAN-like histopathology [23].

PRIMARY MEDIUM VESSEL VASCULITIS

Polyarteritis Nodosa

This less frequently seen MVV affects men and women age 40 to 60 years without sexual preference; a childhood form of PAN (cPAN) is well recognized [58] and in some familial clusters associated with recessive loss-of-function mutations in the gene encoding adenosine deaminase 2 [59]. Most of PAN cases have no known etiology and are labeled as idiopathic PAN. Secondary PAN associates with HBV, HCV infection, human immunodeficiency virus (HIV), cytomegalovirus, parvovirus B19, and human T-lymphotropic virus (HTLV). The frequency of PAN-associated with HBV has dropped in cases from 36% to less than 5% in developed countries due to effected vaccination programs [60], whereas HIV-associated PAN prevails in developed countries [61]. Other than the PAN-associated HBV subgroup, cutaneous PAN and single-organ PAN constitute other acknowledged subgroups (62).

Constitutional symptoms, fever and weight loss and myalgia are almost universal (> 90%), followed by neurologic (75%) and cutaneous manifestations (60%) (Figure 19). It affects almost any other system/organ, like the gastrointestinal (40 - 50%), renal (50%) with renovascular hypertension in < 80%, testicular (20%), musculoskeletal (arthritis in < 75%), ophthalmologic (8%), vascular (claudication, ischemia, necrosis) in 6%, cardiac (cardiomyopathy, pericarditis in 5% and heart failure in $\leq$ 30%, central nervous system (stroke, confusion) in 5% and respiratory (lung infiltrates and pleural effusions) in 3% [58, 63-65] implying multi-organ involvement.

Tissue biopsy of muscle, sural nerve, kidney, liver, testis, and rectum shows segmental neutrophilic muscular vessel vasculitis affecting medium- and small-sized arteries. Even the pathogenic role of immune complexes is considered to play a central role, for unknown reasons PAN does not affect arterioles, capillaries or venules sparing vital organs (absence of capillaritis in lungs and no glomerulonephritis) which together with the negative serology for ANCA differentiates PAN from any other AAV [62]. Active vasculitic lesions are frequently associated with chronic reparative changes that show endarteritis obliterans. Skin lesions are observed in 25 to 60% of patients [66] the commonest of which palpable purpura and erythema of the legs [67]. Subcutaneous leg nodules ranging from 0.5 to 2 cm occur in proximity to blood vessels in 20% of patients. 49.7% of the cases, more often in non-HBV-related PAN (57.8 vs. 35 %). Purpura was the most common type of lesion in patients with PAN with or without an associated HBV infection. Cutaneous vasculitis was found overall in about one-half of their 348-patient cohort of Pagnoux and coworkers with PAN [65], including 57.8% of 225 HBV-seronegative and in 35% of those HBV-seropositive. Interestingly, they also found on multivariate analysis that the presence of cutaneous manifestations at diagnosis, especially nodules, was associated with a higher risk of relapse.

Agard and colleagues [27] reported cutaneous involvement as the initial finding in 11% of 36 patients with MPA and PAN.

Figure 20. Giant Cell Arteritis in a patient who underwent the temporal artery biopsy (seen at the lower arterial tract) and atrophy of surrounding soft tissue. Note the irregularity of the arterial surface.

Cutaneous PAN (CPAN), an indolent form of PAN confined to the skin, is suggested by tender nodules, livedo vasculopathy, livedo racemosa, ulcers, acral gangrene and neuropathy [1, 4, 68]. Deep punch and incisional biopsy demonstrates neutrophilic muscular vessel vasculitis at arterial branch points located at the dermal-subcutis junction or within the subcutis. Macular arteritis [69-72] and lymphocytic thrombophilic arteritis [73] are related variants of CPAN that represent latent or late evolutionary stages of the disease and manifest lymphocytic vasculitis [69, 74]. Nodular vasculitis or erythema induratum of Bazin, a lobular panniculitis and vasculitis of venules and septal veins [75] can be mistaken for CPAN [1, 4, 68]. Their differentiation is possible by considering the relative silhouette and patterns of elastic tissue distribution [76, 77] such that in contrast to the rounded contour of arteries, venous vessels have oval silhouettes with few or no elastic fibers.

LARGE VESSEL VASCULITIS

Giant Cell Arteritis

This disorder occurs in fair-skinned Caucasian individuals of older age females presents with headache, jaw claudication, visual and neurological disturbances resulting from ischemic endarteritis obliterans, and systemic features of malaise, weight loss, and fever due to release of inflammatory cytokines. The cutaneous signs consist of scalp tenderness; blanching, decreased or loss of temporal artery pulses, and cord-like temporal artery thickening (Figure 20) and occasionally distal cutaneous ulceration in the scalp secondary to obliterative

endarteritis. Accurate and timely diagnosis is important because serious morbidity especially loss of vision if the correct treatment with corticosteroids are delayed. Skin biopsies that include muscular vessels of the subcutis and temporal artery biopsies are diagnostic key elements but not necessary for treatment onset if GCA is a highly suspected cases. Areas of normal pathology between lesions, or “skip lesions” may drive to conclude false-negative tissue readings for which the artery biopsy should be at least of 20 mm and analysis should contemplate serial cross-sectioning with an additional 1 - 5% diagnostic yield improvement if a bilateral biopsy is performed [78]. Histopathologically, lesions show granulomatous vasculitis with giant-cell-containing inflammatory infiltrates, while the essential diagnostic features of temporal artery biopsy include segmental inflammation with disruption of media and intima, and fragmentation of the internal elastic lamina.

VARIABLE VESSEL VASCULITIS

Behçet Syndrome

Behçet syndrome is a systemic vasculitis sharing with Cogan syndrome the category of variable vessel vasculitis. It is a chronic relapsing inflammatory disease with high prevalence in the Silk Road countries and of unknown etiology. The clinical features are the recurrent painful oral (aphthous) and genital ulcerations, variable types of ocular inflammation with predominant choroido-retinitis and a plethora of cutaneous manifestations ranging from acneiform lesions, papulopustulosis, pseudofolliculitis, erythema nodosum-like, erythema elevatum diutinum, pyoderma gangrenosum-type lesions, Sweet’s syndrome-like lesions and hyperreactivity to small injuries [79]. This later phenomenon known as the pathergy test is used routinely in the clinical practice as is one of the diagnostic criteria for Behçet syndrome. The pustule-like lesion or papule follows a skin prick by a 20-gauge needle 48 hours later and may be evident during vascular procedures. Behçet syndrome may affect any organ, including the CNS, gastrointestinal system and lungs among others. The histopathology shows variable features like classic leukocytoclastic vasculitis, perivascular inflammation and interstitial infiltrates. In the acne lesions of Behçet LCV and lymphocytic vasculitis was found in 48% of patients compared to acne of patients without Behçet and controls [80]. Other findings may show superficial thrombophlebitis and in the erythema nodosum-like lesions, septal panniculitis with medium vessel vasculitis in up to half of these lesions [81].

SECONDARY VASULITIDES

Connective Tissue Diseases

Lupus Vasculitis

Ramos-Casals and colleagues [10] noted cutaneous vasculitis in 76% of 670 patients with SLE. The commonest cutaneous lesions were erythematous punctate lesions of the fingertips and palms, followed by purpura. Female SLE patients, anti-Ro seropositive, had a 1.63 greater risk of develop cutaneous vasculitis [82]. Compared with SLE controls, those with

cutaneous LV had a higher likelihood of Raynaud phenomenon and ribosomal P protein antibodies, but not greater frequency of kidney or nervous system involvement [83]. Patients with LV typically present with livedo reticularis, anemia, high ESR, and anti-La/SS-B antibodies than SLE patients without vasculitis. Additionally, they are younger, tend to have a higher SLEDAI/SLICC/ACR DI scores with musculoskeletal symptoms and hypocomplementemia, this later with a high sensitivity to detect LV. Lupus nephritis, cardiovascular features and comorbid Sjogren syndrome are significantly linked with the development of LV [84]. Arterioles and post-capillary venules are the most commonly affected by vasculitis, manifested as purpura, vesiculobullous lesions, urticaria, and splinter hemorrhages. Cutaneous ulcers, nodules, digital gangrene, necrotizing livedo reticularis, punctate acral scars, and pyoderma gangrenosum (PG)-like lesions (Figure 21), suggest arterial vessel involvement and multiorgan involvement. There may be p-ANCA and less often c-ANCA-seropositivity. Skin biopsy shows neutrophilic vasculitis with lesions that can resemble either typical LCV or PAN, or coexistence of both small and muscular vessel vasculitis in the same biopsy specimen.

Figure 21. Cutaneous Lupus vasculitis. A young woman with longstanding systemic lupus erythematosus and multiorgan involvement with nodules, pyodermatous ulcers, painful erythematous palmar macules and punctate scars.

Rheumatoid Vasculitis

The extra-articular (ExRA) manifestation of clinically evident RAV were noted in 2% of patients [22] compared to 15% to 31% in postmortem studied cases of RA [85]. The onset occurs in longstanding RA, averaging 10 - 14 years after the outset [86]. Cutaneous RAV is the most common vasculitic type within RA, typically affecting small- and medium size blood vessels. . It should be thought that patients with ‘burned-out’ arthritis with no or very few articular symptoms of disease activity may manifest with RAV in the context of other extra-articular features, like the lungs (pulmonary fibrosis), scleritis, Felty syndrome or co-morbid peripheral vascular disease [87]. Moreover, the odds for developing RAV are the

coexistent peripheral vascular disease, cerebrovascular disease, severe RA (with presence of severe deformities requiring surgery, radiographic evidence of erosions, nodulosis) and use of biologic therapy. Despite the advanced knowledge in the pathogenesis and the introduction of effective biologic therapies, RAV is still associated with increased premature mortality after 5 years of the diagnosis, with mortality of 25% in the 2000's that dropped from a 40% in the 90's. The significant morbidity, in about 36% of patients with RAV, relates to the systemic vessel involvement, in which the devastating inflammatory process, if untreated, leads to the recurrence or further progression in other target organs, while the excessive cytotoxic immune suppression may bring a burden of equal or more morbidity or predispose worse lethal consequences [88]. and is associated with increased premature mortality with mortality in 40 % of patients by 5 years as well as significant morbidity due to both organ damage from vasculitis and consequences of the cytotoxic treatment [89]. Two drugs have proven to decrease the odds for the development of RAV, hydroxychloroquine and aspirin. The former drug, hydroxychloroquine, relies its protective properties as it has protean immunomodulatory action by several mechanisms of action, like the Toll-like receptor inhibition, anti-thrombotic and antilipemic action [90], and the by contributory anticoagulation effects of aspirin. Cutaneous manifestations of RAV are graded mild, moderate, and severe.

Figure 22. Arteritis and small vessel vasculitis leading to geographic ulceration in rheumatoid arthritis vasculitis.

Mild cutaneous RAV presents with nail fold and palmar telangiectasia, thrombosis, minute digital ulceration, petechiae, and livedo reticularis. A well-known presentation are Bywater lesions consisting in periungual infarctions in long-term RA carrying without systemic implications requiring no escalate in the immune suppression [91]. Moderate cases manifest palpable purpura. Severely affected patients present with digital gangrene, nail-fold infarcts, and large cutaneous ulcers (Figure 22). The histopathology of RAV mimics that of polyarteritis nodosa without forming microaneurysms [92]. To define the vasculitic process, three layers of vessel need to be involved, distinguishing this from perivascular infiltrates

without invasive features commonly seen in RA. Neutrophilic proliferation as well as, lymphocytic, and plasmacytic cells infiltrate all layers of the small arteries [93]. Patients with RA and cutaneous LCV alone without RAV, have a better prognosis than those with other ExRA involvement [22]. High acute phase reactants in a RA patient with established disease are the only proving biomarkers contrasting with the rheumatoid factor and anti-citrullinated cyclic peptide antibodies which titers are minimally or not clinically meaningful in RAV. Conversely, the absence of RF and anti-CCP antibodies have an excellent negative predictive value for RAV [94]. Some patients may express a positive anti-nuclear antibody or an anti-perinuclear antibody (atypical), other than then PR3 or MPO antigens suggestive of the underlying vasculitic process targeting other antigens in neutrophil granules. Anti-lactoferrin antibodies have been reported in the latter circumstance [95]. Minocycline-induced cutaneous PAN was reported and associated with the chronic treatment for acne treatment improving after discontinuation of the drug [96].

Drug-Induced Cutaneous Vasculitis

Hypersensitivity vasculitis due to adverse drug reactions manifests as superficial dermal neutrophilic or lymphocytic SVV on skin biopsy, and represents about 20% of cases of cutaneous vasculitis [1, 4, 68, 97]. Tissue eosinophilia is an indicator of drug-induced cutaneous SVV [98].

Tumor Necrosis Factor- α

Tumor necrosis factor- α (TNF- α) inhibitors employed in the treatment of autoimmune and rheumatic diseases [99] were the reported cause of cutaneous vasculitis in 8 patients so treated for 2 to 72 months [100], including four patients with RA, three patients with ulcerative colitis, and one patient with Crohn disease. The commonest presenting manifestation of the patients was palpable purpura, followed by ulcerated lesions, erythematous macules and blisters. After discontinuation of anti-TNF- α , none had recurrent vasculitis. Appearance of ANCA titers in patients under anti-TNF- α therapy should prompt excluding AAV overlap, for which anti-TNF- α is not efficacious, and that requires switching to disease specific therapy [101].

Levamisole

Levamisole was originally introduced as an anthelmintic agent and later employed in Behçet disease and rheumatoid arthritis for immunosuppression. It has been employed in colon cancer enhancing the immunity by potentiating the T-cell mediated immune response. More recently, Levamisole was added to cocaine to potentiate the stimulant effects as it has dopamine agonistic effects provoking a synergistic effect with cocaine [102]. Affected patients have constitutional symptoms, arthralgia, leukopenia, agranulocytosis and cutaneous vasculitis [103, 104] with purpuric lesions of the ears, nose, cheeks, and extremities. The lesions have bright-red borders with central necrosis (Figure 23). Despite the severe and dramatic clinical appearance of these lesions, they usually resolve spontaneously within a few weeks of drug discontinuation but can recur with subsequent contaminated cocaine abuse. Subsequently, clinicians need to differentiate this presentation from other forms of vasculitis,

particularly with GPA, as the degree of immune suppression will differ between both. The degree of skin necrosis has been as severe and large as to require skin grafting, and by removing the offender combined with a short course of corticosteroids will suffice to control the disease, contrasting with the management for GPA, which requires more aggressive immune suppression [105]. One-half of affected patients each demonstrated positive anti-MPO or positive anti-PR3 antibodies [103]. In addition, cocaine contaminated with levamisole by unclear mechanisms, is the mediator of ANCA-mediated vasculitis. The target, differing from AAV, was found to be the neutrophil elastase within the granules eliciting an atypical ANCA positive antibody response. Furthermore, elastase a constituent of neutrophil extracellular traps (NETs) is a target of patients exposed to cocaine/levamisole. It has been suggested that the programmed-cell death of neutrophils by NETs release, which is the extrusion of nuclear (chromosomal material) and mitochondrial DNA containing pro-inflammatory and thrombogenic peptides, is potentiated by cocaine/levamisole. This combination of drugs induces the release of highly immunogenic NETs containing high concentrations of elastase [106]. Other targets have also been reported, like the antiphospholipid antibodies found in 63% of patients [104], and anti-C1q antibodies [107].

Figure 23. Levamisole-induced vasculitis shows histologic signs of a vaso-occlusive disorder and vasculitis.

AUTOINFLAMMATORY DISEASES

Autoinflammatory diseases (AD) comprise a heterogeneous group of diseases in which inflammation is triggered spontaneously and periodically with activation of the innate immune system. Most of them follow a well-defined Mendelian pattern of inheritance while others do not. The common onset of AD starts at early ages and in others, the onset is not seen until early or full adulthood. Although in most of the AD, the prevailing cutaneous expression reveals the group of neutrophilic dermatoses or urticarial presentation, few cases and series report true vasculitic processes, revealing the heterogeneity of disease phenotype and perhaps expressing a process outside the main pathogenesis.

Most notably of this group, Hyper-IgD syndrome has revealed true vasculitis. Hyper-IgD syndrome is characterized by periodic fever flares of 3 - 7 days, in infants and accompanied by arthralgia, abdominal pain, splenomegaly, cervical lymphadenopathy aphthous ulcers and maculopapular rash, annular erythema, palpable purpura and urticarial lesions [108]. The histopathology revealed perivascular infiltrates of variable numbers of lymphocytes and polymorphonuclear neutrophils fibrin deposits and red blood cell extravasation in a case report and analog findings in 7 out of 17 cases [109].

In cryopyrin-associated periodic syndromes (CAPS), which is a continuum of three disorders with the mutations in the NLRP3/CIAS1 gene, familial cold autoinflammatory syndrome (FCAS), Muckle Wells syndrome (MWS) and neonatal onset multisystem inflammatory disease/chronic infantile neurological cutaneous articular syndrome (NOMID/CINCA), neutrophils urticarial dermatoses is the classical feature. Predominant perivascular and peri-ecrine and interstitial neutrophil infiltration is seen and very few lymphocytes/eosinophils. The deep dermis has also engorged vessels also filled with neutrophils [110]. Cases of cutaneous vasculitis were reported in MWS and CINCA/NOMID syndrome in which other organs are also compromised [111].

TNF receptor-associated periodic syndrome (TRAPS) is an autosomal dominant disorder consisting of periodic fever episodes lasting from 3 to 21 days, and in which manifestations show pleuritic chest pain, abdominal pain, conjunctivitis, periorbital edema, monoarthritis, testicular pain, myalgia, papulomacular and urticarial rash. A report revealed small vessel vasculitis and panniculitis in a 66-year old patient diagnosed with TRAPS with migratory macular erythematous rash and with positive ANCA against elastase, successfully treated with etanercept [112].

IGG4 RELATED DISEASE

The analogy in the histopathology of two small vessel vasculitides granuloma faciale (GF) and erythema elevatum diutinum (EED) with IgG4-related disease suggests that they might belong to the same spectrum. The two vasculitides, considered as a single disease with different presentations, share two distinctive features: small vasculitic lesions and concentric fibrotic processing. Granuloma faciale affects preferentially the face with one or multiple erythematous purplish plaques, and with lesions showing dense inflammatory infiltrate with neutrophils, eosinophils, lymphocytes and plasma cells and formation of perivascular concentric fibrosis.

Similarly, erythema elevatum diutinum presents with plaques nodular lesions preferring the trunk and lower extremities and with predominant neutrophils in the infiltrate. GF has been linked with eosinophilic angiocentric fibrosis, an eosinophil-rich infiltrate with perivascular fibrosis characteristically present in the upper respiratory tract. This latter has also been proposed being an expression of IgG4-related disease and the hypothetical link between both surmounts to the functional role of IgG4 with allergic responses and the production of IL-5 attracting eosinophils with subsequent fibrosing process formation. IgG4-related disease is a systemic illness causing mass lesions in different organs, like the pancreas, exocrine glands, lymph nodes peribiliary infiltrates, interstitial nephritis and other tissues, and associated with a predominant lymphoplasmacytic cell infiltrate producing excessive IgG4,

eosinophils, storiform fibrosis and obliterative thrombophlebitis. The quantity of lymphoplasmacytic infiltrates, serum IgG4 levels, the IgG4/IgG ratio are diagnostic criteria [113] and to test whether EED and GF fulfilled these, tissues of 32 patients (GF, n = 25; EED, n = 7) were analyzed with Immunohistochemistry. However, results failed to provide confirmatory evidence in the two vasculitides attributable to the stringent diagnostic criteria and to the retrospective nature of the study [114]. In another report, however, the results in tissues of GF and EED, 7 (22.6%) out of 31 patients fulfilled criteria for IgG-related disease (IgG4/IgG ratio > 40% and > 50 cells with IgG4 IHC per high power field), but none in the EED patients. Curiously all patients were males and with recurrent multiple lesions without other organ involvement suggestive of a localized form of IgG4-related disease might be expressed as GF in some subpopulations [115]. Further prospective and larger multicentric studies are required supporting this concept.

Table 5. Clinical, pathologic, and laboratory findings indicating a high probability of systemic disease¹

Clinical signs or symptoms	Suspected Systemic Vasculitis Syndrome
High fever	Infection, systemic inflammatory disorders
Paresthesias, foot drop	EGPA, PAN
Abdominal pain	HSP, EGPA, MPA, PAN, RV, LV, BD
Frank arthritis	RV, infection, PAN, systemic inflammatory disorder
Hypertension	PAN
Purpura above waist, upper extremities	HSP, MPA, GPA, EGPA
> 1 type of vasculitic lesion*	HSP, MPA, GPA, EGPA, RV, LV, BD
Punctate palmar lesions	LV
Laboratory evaluation	Suspected Systemic Vasculitis Syndrome
ESR > 40mm/hr	Infection, hematologic malignancies, systemic inflammatory disorders
Elevated RF, cryoglobulins and low complement	CV
Chest x-ray: infiltrates or cavities	GPA (fixed infiltrates), EGPA (non-fixed infiltrates), MPA, malignancy
Hematuria and/or proteinuria and/or abnormal creatinine	Dermal-renal vasculitis syndrome: GPA, MPA, HSP, SLE
Hypocomplementemia	UV associated with SLE, RV, CV, infective endocarditis
Abnormal blood count	Infection, hematologic malignancy, systemic inflammatory disorders
cANCA (PR3)	GPA
pANCA (MPO)	MPA, EGPA
Eosinophilia, elevated IgE, elevated RF	EGPA
Histologic Examination	Suspected Systemic Vasculitis Syndrome
Deep dermal and/or subcutaneous small and/or muscular vessel vasculitis	Systemic vasculitis syndrome (GPA, EGPA, MPA, CV, BD, RV, LV, septic vasculitis), malignancy associated
Palisaded neutrophilic (extravascular) granulomatous dermatitis	GPA, EGPA, LV, RV
Tissue neutrophilia	SLE, infection
Tissue eosinophilia	EGPA and drug induced vasculitis
Direct immunofluorescence	Suspected Systemic Vasculitis Syndrome
Isolated or predominate IgA vascular deposits	HSP
Lupus band (IgG, IgM, and/or C3 at the BMZ)	LV, UV associated with SLE

BD = Behcet disease; BMZ = basement membrane zone; c-ANCA = cytoplasmic anti-neutrophil cytoplasmic antibody; CV = cryoglobulinemic vasculitis; EGPA = Eosinophilic granulomatosis with polyangiitis; ESR = erythrocyte sedimentation rate; GPA = Granulomatosis with polyangiitis; HSP = Henoch-Schonlein purpura; LV = lupus vasculitis; MPA = microscopic polyangiitis; MPO = myeloperoxidase; PAN = polyarteritis nodosa; p-ANCA = perinuclear pattern of anti-neutrophil cytoplasmic antibody; PR-3 = antiproteinase-3; RF = rheumatoid factor; RV = rheumatoid vasculitis; SLE = systemic lupus erythematosus; UV = urticarial vasculitis

¹Adapted from Chen and Carlson et al. [4].

SYSTEMIC MALIGNANCY

Lymphoproliferative, myeloproliferative, and carcinomatous tumors comprise < 5% of paraneoplastic cutaneous vasculitis (Figure 24), a diagnosis that may be considered in patients with recurrent purpura, hematologic abnormalities including cytopenia, monoclonal gammopathy, immature blood cells; hematuria, abnormal tissue or nodal masses on imaging studies, and refractory responses to immune therapies. There are three such categories of patients including, those with true paraneoplastic vasculitic syndromes wherein the vasculitis improves with extirpation or treatment of the tumor; vasculitis masquerading as malignancy such as lung masses in GPA; and malignancy masquerading as vasculitides as in emboli from an atrial myxoma and superficial migratory thrombophlebitis with pancreatic cancer. Most paraneoplastic cutaneous vasculitic syndromes are the result of a paraproteinemia secondary to lymphoproliferative disorders, including cryoglobulinemia in association with lymphocytic lymphoma and Waldenström macroglobulinemia.

Figure 24. Myelodysplastic syndrome presenting as erythema elevatum diutinum. A large ulcerative tumor shows localized fibrosing leukocytoclastic vasculitis.

PROGNOSIS

There are clinical and histologic predictors for the prognosis of cutaneous vasculitis that suggest the likelihood of concomitant or later systemic vasculitis [1, 18, 116] as shown in Table 5. The distinction between localized cutaneous and systemic vasculitis is important since the former carries a relatively favorable outcome, while the latter conveys the likelihood of permanent organ damage, increased morbidity and mortality. About 20% to 40% of patient with cutaneous vasculitis have concomitant limited systemic vasculitis notably kidney such as so called renal-dermal vasculitis while the likelihood of chronicity and systemic progression

is enhanced when there is coexisting CTD, cryoglobulinemia, frank ulceration [117], arthralgia [19], more than one form of cutaneous vasculitic lesion such as ulceration and palpable purpura, putative muscular and SVV, normal serum IgA levels [17], paresthesia, fever, painless lesions [19] and cutaneous necrosis [118]. Histologically, the severity of vessel injury in cutaneous vasculitis correlates with the clinical severity and course [117, 119]. Others have noted histopathological changes of LCV were not predictive of extracutaneous involvement [120]. Lesional IgA deposits by DIF predict proteinuria and subsequent renal involvement [121]. Up to 60% of patients presenting with cutaneous vasculitis on skin biopsy have SVV restricted to the dermis while the remainder have deep dermal and pannicular SVV and muscular vessel involvement [122].

THERAPY

Therapy depends upon the nature and severity of the vasculitis. Mild hypersensitivity due to drug reactions should be treated with discontinuation of the offending agents, antihistamines for urticaria-associated pruritus, and a short course of corticosteroids in more severe cases. Simple observation may be adequate for mild cases and transient lesions of HSP/IgAV-related purpura. Non-steroidal anti-inflammatory agents, colchicine, antihistamines, and dapsone may be employed in chronic cutaneous vasculitis without recognizable cause and in selected patients prior to administration of corticosteroids and cytotoxic drugs. Rituximab has equivalent remission-induction efficacy as cyclophosphamide in AAV each in conjunction with corticosteroids [123]. Morphologic alternations of the vessel wall lumina and perivascular areas may be useful in treatment strategy. Healed arteritis with intimal thickening due to luminal occlusion should suggest the need for anticoagulation and vascular dilating agents, whereas pathologically confirmed acute and subacute arteritis generally warrants combination immunosuppressive therapy to suppress ongoing vascular inflammation and tissue damage.

Chapter 212

THE CLINICAL APPROACH TO PATIENTS WITH VASCULITIS

David S. Younger*, MD, MPH, MS

Department of Neurology, Division of Neuroepidemiology, New York University School of Medicine, and the College of Global Public Health, New York University; and the Department of Health Policy and Management, School of Public Health, City University of New York, New York, New York, USA

ABSTRACT

The systemic vasculitides are a heterogeneous group of disorders. Pathologically defined by the presence of vascular inflammatory infiltrate, primary vasculitides occur in the absence of a known cause or associated disease state, while secondary vasculitides occur in association with known underlying disorders and disease triggers. The vasculitic process is often systemic however vascular inflammation may be confined to an isolated organ system such as the kidney or even central nervous system. This chapter provides an overview of the approach to patients with systemic vasculitis including the clinical presentation, differential diagnosis, imaging and histopathologic evaluation, and short- and long-term treatment-related complications.

INTRODUCTION

The primary systemic vasculitides are a diverse group of multisystem syndromes characterized according to the size of the blood vessels involved and the organ systems affected. Inflammation in the blood vessels can lead to diminished blood flow or vessel occlusion resulting in ischemia, necrosis and subsequent tissue damage. The blood vessels themselves can be damaged in vasculitis resulting in permanent stenosis, aneurysmal change and vessel rupture. Any combination of vessels from large arteries to tiny venules and

* Corresponding Author's Emails: david.younger@nyumc.org; <http://www.davidsyounger.com>.

capillaries may be involved in the inflammatory process. The 2012 Revised Chapel Hill Consensus Conference (CHCC) [1] provides useful nosology for the primary vasculitides based upon the caliber of the vessels, both arteries and veins, involves. Small vessel vasculitis (SVV) includes granulomatosis with polyangiitis (GPA) (Wegener type)], microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) (Churg-Strauss syndrome [CSS]), known collectively as anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV).

Vasculitic disorders associated with immune complexes (IC) include IgA vasculitis (IgAV) (Henoch-Schönlein purpura [HSP]), cryoglobulinemic vasculitis (CV), and hypocomplementemic urticarial vasculitis (HUV) associated with C1q antibodies. Vasculitis without a predominant vessel size and caliber, respectively from small to large, involving arteries, veins and capillaries, comprises the category of variable vessel vasculitis (VVV), characteristic of Behçet disease (BD) and Cogan syndrome. Medium vessel vasculitides (MVV), exemplified by polyarteritis nodosa (PAN) also includes Kawasaki disease (KD) in children. Large vessel vasculitides (LVV) are represented by giant cell arteritis (GCA), and Takayasu arteritis (TAK). Vascular inflammation confirmed to a single organ system such as the kidney, peripheral nerves, brain or vessel such as IgG4 related aortitis, are deemed single organ vasculitides (SOV).

In 2008, the Pediatric Rheumatology European Society (PRES) and the European League against Rheumatism (EULAR) and the Pediatric Rheumatology International Trials Organization (PRINTO) reported methodology and overall clinical, laboratory and radiographic characteristics for several childhood systemic vasculitides [2] followed by a final validated classification [3] based upon vessel size, similar to the CHCC nomenclature [1].

This chapter provides an overview of the clinical approach and management of patients with primary systemic vasculitis including aspects of the clinical presentation, differential diagnosis, imaging, histopathologic evaluation, and short- and long-term treatment-related complications.

HISTORY AND EXAMINATION

Clinical acumen combined with a thorough history and physical exam is essential to making the diagnosis and defining the correct testing to complete the diagnosis and assess the extent of disease. Thus, while it may seem obvious, the first challenge in the diagnosis of primary systemic vasculitis is in fact considering it as a possible diagnosis. The diagnosis is often delayed as more common causes of multi-system disease like infections and malignancies are investigated. One population-based study reported a median time interval between the onset of symptoms and diagnosis of 11 months (range, 1 to 50 months) in TAK [4]. The past decade has witnessed a decrease in the time to diagnosis of AAV from a mean of 17 months to 4 months; however delays in diagnosis occur in subgroups of patients with flu-like prodromal and upper respiratory symptoms [5]. Failure to make a timely diagnosis can have devastating consequences such as blindness due to unrecognized GCA, renal failure caused by untreated AAV, and death due to a rupture of an unrecognized mesenteric aneurysm caused by PAN.

Despite significant overlap, vasculitic disorders generally manifest characteristic patterns of organ involvement. Fever, weight loss, fatigue, arthritis, skin rash, peripheral (PNS) and central nervous (CNS) manifestations are common symptoms and signs of systemic vasculitides. In spite of expected disparities in vessel involvement and resultant end-organ damage, in one cohort of 800 patients with AAV, PAN, GCA, and TAK [6], greater than 30% of those with LVV, and more than 70% of patients with SVV and MVV experienced constitutional symptoms at the time of diagnosis. Certain clinical presentations should prompt swift evaluation for systemic vasculitis such as mononeuritis multiplex, pulmonary-renal syndrome with a rapidly progressive glomerulonephritis, alveolar hemorrhage and infarction in multiple vascular beds.

The presence of concomitant infection should be sought in suspected patients. Both hepatitis B (HBV) and C virus (HCV) infections are associated with concomitant IC-mediated vasculitis, and there are recognized relationships between HBV and PAN, and HCV contributes to the pathogenesis of mixed cryoglobulinemic vasculitis. Although effective vaccine programs in the developed world may already have dramatically reduced the rate of acute HBV infection, large cohort studies have found an association between HBV and PAN in up to a third of patients [7]. Hepatitis B surface antigen (HBsAg) and antibody (HBsAb), and core antibody (HBcAb), and HCV should thus all be included in the routine evaluation of such patients. Human immunodeficiency virus-type 1 (HIV-1) is an associated cause of vascular inflammation predominating in SVV [8]; and in the absence of systemic vasculitis, patients with HIV may demonstrate ANCA-seropositivity. HIV-infected patients become susceptible to opportunistic infection including cytomegalovirus (CMV). The latter may be associated with true vasculitis with discernible CMV inclusions in the inflammatory infiltrate, especially in those with established acquired immune deficiency syndrome (AIDS), and skin, gastrointestinal, pulmonary, and CNS involvement. Other opportunistic infections that cause vasculitis in the immunocompromised hosts include *Pneumocystis jirovecii* and *Toxoplasma gondii*. Endovascular infection by bacterial or fungal agents in the course of endocarditis and mycotic aneurysms can mimic systemic vasculitis. Koenig and colleagues [9] identified a *Burkholderia*-like gram-negative bacterial strain in the temporal arteries of subjects with GCA. Two other pathogens, *Treponema pallidum*, the spirochete pathogen of tertiary syphilis, and *Mycobacterium tuberculosis* (TB), both contribute to the development of aortitis and LVV, with histologically evident chronic granulomatous in endemic areas where the prevalence of TAK is highest.

A knowledge of potentially offending medications or known drug abuse may give valuable clues to the origin of vasculitis in susceptible patients. There is an ever-growing list of medications associated with hypersensitivity vasculitis, the clinical presentation of which is usually self-limited and resolves once the causative agent has been identified and removed. The prescription drugs hydralazine and propylthiouracil are both associated with ANCA-seropositivity but not true vasculitis. One important distinction in the diagnosis of drug-induced AAV is that unlike idiopathic AAV, those associated with drug-induced ANCA-seropositivity often have antibodies against more than one antigen [10]. The acute onset of headache and focal neurological deficit in a known cocaine abuser should lead to consideration of cocaine-induced vasospasm with cerebral hemorrhage. Such patients will often have midline destructive nasal sinus lesions. Cocaine-induced midline destructive lesions (CIMDL) may also resemble GPA, further complicating the distinction between CIMDL and AAV is often present ANCA-seropositivity. Cocaine-induced CIMDL can be

associated with p-ANCA, c-ANCA or both. The most common autoantibody in CIMDL, occurring in 84% of patients in one study, was atypical p-ANCA directed against human neutrophil elastase (HNE) [11]. Requesting specific ANCA serology by the immunofluorescence technique (IFT), and not just the ANCA pattern, avoids misdiagnosis between CIMDL and sino-nasal GPA.

Fever, purpuric rash, acute renal failure, and neurologic involvement may also be the clue to SVV. While prothrombotic disorders may mimic systemic vasculitis, the manifestations of anti-phospholipid syndrome (APS) can overlap with systemic vasculitis. Affected patients with catastrophic APS can present with pulmonary-renal syndrome, and unlike those with SVV, such patients require anti-coagulation. The non-criterion manifestations of APS-like skin ulcers and emboli from verrucous valvular heart disease can appear grossly similar to vasculitic lesions however skin biopsy which instead shows *in situ* thrombi instead of vascular inflammation distinguishes the two entities.

Ischemic limb pain and claudication may well be the presenting manifestations of MVV and LVV in older patients with diabetes, hyperlipidemia, hypertension and tobacco use that is due to atherosclerosis. Moreover, both vasculitis and atherosclerosis may reveal abnormalities on non-invasive vascular imaging and contrast angiography studies. While the suspicion of primary systemic vasculitis should generally be reserved for younger patients and older individuals lacking traditional cardiovascular risk factors, the exception occurs in cholesterol crystal embolism [12]. Such patients manifest distal embolization of atherosclerotic plaques leading to livedo skin rash, digital ischemic, visual and renal manifestations. Arteriolar cholesterol clefts are demonstrable in tissue biopsy of skin, muscle, and cutaneous nerve specimens.

A history of malignancy or the suspicion of cancer may be indispensable and life-saving. The majority of malignancy-associated vasculitides occur in conjunction with hematologic malignancies and myelodysplastic syndromes. A reported 4.5% to 8% of patients with lymphoproliferative disease developed primary systemic vasculitis with renal, cerebral, pulmonary, and cutaneous involvement [13]. There are reports of homology between the genetic sequences of serine proteinase-3, the antigenic target in GPA, and myeloblastin a protein found in certain human leukemic cells, explaining in part the association between hematologic malignancy and systemic vasculitis [14]. Hairy cell leukemia may be the proximate cause of necrotizing systemic vasculitis. Other tumors can cause constitutional symptoms mimicking vasculitis and embolic phenomena including atrial myxoma, so noted in more than 30% of patients that manifested fever, arthralgia and weight loss in association with laboratory features of acute inflammation [15]. These benign tumors express increased levels of IL-6, a pro-inflammatory cytokine implicated in the pathogenesis of LVV such as GCA. A history of thyroid endocrinopathy may lead to consideration of autoimmune thyroid disease and Hashimoto thyroiditis and encephalopathy.

Although very rare, the literature describes cases of Hashimoto encephalopathy attesting to its occurrence [16]. Affected patients present with seizures, stroke-like episodes, transient focal and global neurological deficits, and a variety of neuropsychiatric disturbance from dementia to hallucinations and psychosis. The encephalopathy evolves with concomitantly elevated anti-thyroid peroxidase antibodies, independent from hormonal thyroid function setting it apart from thyrotoxicosis and myxedema. Albeit rare, such cases may be indistinguishable from CNS vasculitis and share an autoimmune vasculitic etiopathogenesis.

The autoimmune encephalitides [17], so suggested by cognitive, neuropsychiatric complaints and seizures, are clinically and histopathologically associated with serum and intrathecal antibodies to intracellular and surface neuronal antigens, and constituents of the limbic system neuropil. This has led to a reconsideration of a number of neuropsychiatric and neurocognitive disorders as having shared mechanisms of origin. While there are no convincing cases of vasculitis autoimmune encephalitis, there may be difficulty in clinically distinguishing them from primary CNS vasculitis.

A detailed genetic pedigree may not be practical in all cases, but knowledge of a familial disorders or genetic syndromes affecting the vasculature resembling vasculitides may signal the need for associated targeted genetic testing in given patients. At least three congenital disorders, Ehlers-Danlos syndrome, type-4 Loeys-Dietz and Marfan syndrome [18-20], all enter in to the differential diagnosis of LVV and idiopathic aortitis, also a component of the IgG4-related disorders (IgG4-RD); and a fourth disorder termed Grange syndrome that resembles PAN.

LABORATORY EVALUATION

Accurate diagnosis depends upon familiarity with the myriad of clinical features of the various vasculitides together with results of carefully selected laboratory studies including screening metabolic, autoimmune and infectious serology, followed by appropriate vascular imaging studies, and appropriate tissue biopsies or sampling of body fluids.

Blood studies will often reflect the severity and type of immunological storm due to underlying primary vasculitis in analysis of a complete blood count (CBC) and differential, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), antinuclear antibody (ANA), basic metabolic panel, ANCA by IFT and enzyme-linked immunosorbent antibody (ELISA) serology specific for proteinase-3 (PR3) and myeloperoxidase (MPO); T- and B-cell subset quantitation; C1q binding and Raji cell circulating immune complexes and C3, C4, and CH50 complement protein levels; quantitative immunoglobulins, subsets, and immunofixation (IFE); with rheumatoid factor (RF) titers, cryoglobulins, serologic analysis for HBV, HCV, HIV, lupus and anticardiolipin antibodies, acute and convalescent *Borrelia* and coinfectious serology; and human leukocyte antibody (HLA) alleles appropriate for different types of primary vasculitides.

Urine should be obtained for spot analysis and 24-hour collection for chemical and cellular microscopic constituents to screen for renal impairment.

The *radiologic evaluation* of patients with primary vasculitis should include color-Doppler sonography (CDS), and 3-Tesla (T) magnetic resonance imaging (MRI) combined with angiography (MRA) or CT angiography (CTA) to assess the temporal arteries and great vessels. Digital subtraction angiography (DSA) of individual vascular organ beds can be employed to visualize the vessel walls and luminal changes. Mural changes with vessel wall thickening correlate with early inflammation while vascular luminal stenoses and aneurysm formation indicate late vasculitic complications. ¹⁸Fluorodeoxyglucose positron emission tomography (PET) detects metabolically active inflammatory cells infiltrating vessel walls in affected patients especially in large vessels. However, the extent of disease and monitoring of luminal changes is best appreciated by employing a combination of PET and DSA techniques.

Likewise the combination of nuclear medicine cerebral perfusion with single photon emission CT (SPECT) and PET fused with MRI provides a unique estimation of perfusion across the blood-brain barrier in relation to cerebral regional metabolism.

Cerebrospinal fluid (CSF) obtained in patients with presumed CNS involvement, should be obtained atraumatically and sampled for an extensive panel of constituents with an extra tube placed in a negative 80 degree Celsius freezer for future analysis or to replace specimens lost in transport. This includes analysis of CSF total protein and glucose levels, white blood cell and red blood cell counts, IgG and albumin levels, oligoclonal bands, cytology, bacterial gram stain, latex agglutination of meningitis-associated bacterial antigens related to *Group B strep*, *Strep pneumoniae*, *Haemophilus influenza* (Type b), *Neisseria meningitidis* (Groups A,B,C,Y & W135) and *E. coli* K1 infection; India ink preparation, cryptococcal antigen, acid-fast stains; bacterial, fungal, parasitic, and TB cultures. New York State has a viral encephalitis panel that includes Adenovirus, West Nile virus, HSV 1 and 2, CMV,VZV, EBV, and HHV6 DNA viruses, as well as Eastern Equine Encephalitis, Saint Louis Encephalitis and Enterovirus RNA viruses, all analyzed by real-time polymerase-chain reaction (PCR). Patients suspected of *Borrelia burgdorferi* infection undergo paired serologic and PCR analysis of CSF and serum to demonstrate intrathecal production of *Borrelia*-specific antibodies [21]. A commercially available panel of CNS antibodies for patients with autoimmune or paraneoplastic dementia with or without sensory and motor neuronopathy or dysautonomia includes N-methyl-D-aspartate receptor (NMDA-R), voltage-gated potassium channel (VGKC)-complex, glutamic acid decarboxylase (GAD) 65, gamma-amino butyric acid beta receptor (GABA-R), anti- α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPA), anti-neuronal nuclear antibody (ANNA)-1, -2, -3; anti-glial nuclear antibody (AGNA)-1; Purkinje cell cytoplasmic antibody (PCA) types 2 and Tr; amphiphysin, N and P/Q-type calcium channels, ganglionic neuronal and muscle acetyl choline receptors (AChR), and collapsin response-mediated protein-5-(CRMP-5-IgG).

Tissue biopsy is important in defining the type, extent and character of the inflammatory process and categorizing the underlying systemic vasculitic disorder. In AAV, histologic evidence of necrotizing SVV with accompanying granulomatous inflammation noted in GPA can be used to support the diagnosis in conjunction with clinical and serologic information. Although nasal, sinus and upper airway involvement in GPA may be noted overall in 92% of patients at onset of disease [22], tissue biopsy of these regions is associated with vasculitis and necrosis in only 23% of upper airway biopsy specimens; vasculitis and granulomatous inflammation in 21%; and vasculitis together with necrosis and granulomatous inflammation in only 16%. The small amount of tissue available in biopsy specimens from areas of the head and neck make it surprisingly difficult or impossible to identify the classical pathological features of GPA in some patients. By comparison, renal biopsy in patients with GPA show varying degrees of segmental necrotizing glomerulonephritis in 80% of tissue. In the absence of renal involvement, targeted biopsy of radiographically abnormal lung parenchyma via a thorascopic or open lung biopsy technique showed granulomatous changes in 22% and capillaritis in 31% of those so studied [20] compared to the efficacy of transbronchial biopsy in establishing the diagnosis of pulmonary vasculitis in 10% of suspected tissues [23].

The finding of focal, segmental necrotizing vasculitis in medium-sized arteries confirms the diagnosis of PAN in suspected patients. Angiographic demonstration of microaneurysm formation is an acceptable surrogate to the histopathologic confirmation when tissue cannot be readily obtained [24]. Histologically-proven PAN is ascertained in 70% of patients by

nerve, muscle or skin tissue biopsy in one large cohort [25]. Of 129 patients underwent nerve biopsy including 108 with peripheral neuropathy and 21 without peripheral neuropathy, vasculitic lesions were noted respectively in 83% and 81% of patients compared to muscle biopsy which showed vasculitis respectively in 68% and 60%. Angiography showed renal and gastrointestinal microaneurysms or stenosis respectively in 66% and 57% of patients. While PAN frequently involves the gastrointestinal tract especially the small intestine, biopsy of visually apparent lesions on luminal exam rarely provide histopathologic confirmation of vasculitis [26]. Renal biopsy may be negative even in patients with frank organ involvement due to sampling error. Unlike AAV, where the histopathologic renal lesion is the kidney glomerulus, microaneurysm formation due to PAN increases the risk of bleeding associated with renal biopsy.

Histopathologic evidence of vascular wall infiltration by giant cells at the junction of the intima and media, leading to thrombosis, intimal hyperplasia, and fibrosis [27] is the gold standard method of GCA diagnosis. Accordingly, temporal artery biopsy is recommended for all patients with suspected GCA [28]. The sensitivity of temporal artery biopsy in GCA has been estimated to be 85% [29]. Evidence in support of unilateral as compared to bilateral temporal artery biopsy is lacking, leaving it up to the judgment of the treating physician. Temporal artery ultrasonography can be used to guide the surgeon to the arterial segment with the clearest halo sign in performance of temporal artery biopsy [30], however the discontinuous nature of inflammation in GCA leading to skip lesions may still lead to unforeseen false-negative results when the tissue specimen is of insufficient length and multiple sections are not examined. Certain clinical features, such as the presence of jaw claudication can increase the positivity predictive value of a temporal artery biopsy. Arteritis can be observed histologically even after several weeks of high dose corticosteroid therapy [31]. Notwithstanding, the heightened risk of ischemic complications culminating in irreversible visual loss in early untreated GCA has led to the recommendations for prompt administration of high-dose corticosteroid therapy while awaiting tissue biopsy results.

Skin biopsy can be performed for IF analysis of vessel walls to search for microscopic analysis for leukocytoclasia, Ig and complement deposition. Two 3 mm punch skin biopsies of along the distal calf and proximal thigh fixed in anti-protein-gene-product 9.5 (PGP 9.5) solution will discern epidermal nerve fiber depletion useful in the designation of small and large fiber neuropathy, and in the selection of patient who should undergo surgical biopsy of the sural nerve or branch of the superficial fibular sensory nerve and corresponding soleus and peroneus brevis muscle to search for vasculitic lesions and confirm the neuropathic or myopathic changes found on electrodiagnostic studies. Adults and children with CNS involvement whether clinically, by MRI, SPECT, PET imaging of the brain, cerebral angiography, or CSF examination, especially in the setting of acute mental change, new focal neurological deficit, CSF protein content >100 mg/dL or pleocytosis, may be candidates for empiric therapy for primary CNS angiitis [32] or combined leptomeningeal and brain biopsy to diagnose granulomatous or non-granulomatous necrotizing arteritis [33-34].

TREATMENT

Most experts concur with the following three principles to guide management of patients. First, vasculitis is a potentially serious disorder with a propensity for permanent disability owing to tissue ischemia and infarction. Second, undiagnosed and untreated, the outcome of vasculitis is potentially fatal. Third, a favorable response to an empiric course of immunosuppressive and immunomodulating therapy should not be considered a substitute for the histopathologic confirmation of vasculitis. Physicians treating vasculitides must choose the sequence and combination of available immunosuppressant and immunomodulating therapies to induce and sustain remission and treat relapses, recognizing the possible beneficial and adverse effects. Recommended treatment options for the different categories of vasculitis are summarized in Table 1.

The standard of care for the treatment of vasculitides, notably AAV, has been evolving in response to many factors [35]:

First, the steady influx of data from multicenter, national and international collaborative, evidence-based randomized clinical trials (RCT) and observational cohorts in adult vasculitides, notably from the French Vasculitis Study Group (FVSG) database, United States-Canadian Vasculitis Clinical Research Consortium (VCRC), European Vasculitis Study Society (EUVAS), the European League Against Rheumatism (EULAR), The French Vasculitis Cohort of Patients with Primary Vasculitis of the Central Nervous System (COVAC), and the Diagnostic and Classification Criteria in Vasculitis Study (DCVAS). Childhood vasculitides have been represented by the Pediatric Vasculitis Initiative (PedVas), a Canadian and United Kingdom collaborative study of ARChiVe Investigators Network within the PedVas Initiative and ARChiVe registry, including BrainWorks and DCVAS, of pediatric and adult cases of AAV (GPA) and PACNS (NIH identifier, NCT02006134). PedVas has been prospectively collecting clinical and biobank data of registered cases within 12 months of study entry since 2013.

Second, while many vasculitides still lack well-validated measures of disease activity or state for use in clinical trials, there have nonetheless been advances in standardized approaches to conducting clinical trials as advocated by the EULAR and its collaborators worldwide [36]. Moreover, the Vasculitis Working Group of the Outcome Measures in Rheumatology (OMERACT) initiative is actively pursuing projects to advance development of valid measures in the vasculitides [37-39], such as disease-specific self-reported patient-related outcomes (PRO) applicable to AAV to distinguish treatments of varying efficacy, included among them, Health Related Quality of Life (HRQoL) measures, that are further separable by the caliber of vessels involved [40, 41]. Children's self-reported HRQoL measured by the Pediatric Quality of Life Inventory Version 4.0 (PedsQL) Generic Scores Scales, repeatedly measured over time in pediatric inflammatory brain disease (IBrainD) [42], including cPACNS, shows poor HRQoL scores in >50% of patients at that associates with cognitive dysfunction as the most presenting symptom, as well as, small vessel cPACNS (SV-cPACNS) [43].

Third, the influence of gene-wide association studies (GWAS) and biobank data such as the UK Biobank to elucidate risk gene loci, single nucleotide polymorphism (SNP) and human HLA polymorphisms in disease clusters and population cohorts [44]. Such inherited and environmental factors, gene-gene interactions, epigenetic factors, and other influences

upon the immunopathogenesis of vasculitides have had important theoretical importance for the performance of RCTs in vasculitides subtypes, as well as, relevance for screening studies and timing of therapy.

Fourth, historically, the introduction of effective therapy for AAV, beginning with corticosteroids in 1948, and cyclophosphamide two decades later, together with adjunctive therapies, transformed the outcome of AAV with five-year rates approaching 80% [45]. The AAVs were thus transformed into chronic relapsing disorders with progressive organ damage and disability. Hope for a better treatment was heralded by the effectiveness of a daily oral regimen of 2 mg/kg/day of oral cyclophosphamide and prednisone in GPA that served as a template for the treatment of virtually all types of systemic vasculitis for decades. However, almost all patients had serious morbidity from irreversible features of their disease or side effects of treatment, including the cumulative exposure to corticosteroids leading to osteoporosis and bone fractures; and cytotoxic therapy-related chronic myelosuppression, infection, urothelial malignancy, and infertility [46, 47]. Three later adjustments in the use of cyclophosphamide in AAV were instructive. One was the sequential replacement of cyclophosphamide by azathioprine [48]. A second was the replacement of cyclophosphamide by methotrexate by for early systemic disease without critical organ manifestations in the NORAM study [49]. A third was pulsed intravenous cyclophosphamide with a dose reduction in patients >60 years of age and renal impairment rather than daily oral cyclophosphamide as in the CYCLOPS study [50], enabling a cumulative dose reduction of approximately one-half. Follow-up analyses [51], however showed that reduced cyclophosphamide dose was associated with a higher risk of relapse, while methotrexate was associated with less effective disease control than with cyclophosphamide induction [52]; neither with increased long-term morbidity or mortality.

Fourth, the licensing of rituximab for the treatment of AAV was the most significant recent achievement but the optimal treatment strategy after rituximab induction-remission awaits delineation. Rituximab is a chimeric monoclonal anti-CD20 antibody that selectively depletes B-cells, but not plasma cells. The Rituximab in ANCA-Associated Vasculitis (RAVE) Study [53] found that rituximab was not inferior to daily cyclophosphamide treatment for induction of remission in severe AAV and possibly superior in relapsing disease. The Rituximab Versus Cyclophosphamide in ANCA-Associated Vasculitis (RITUXVAS) [54] demonstrated non-superiority of rituximab to standard intravenous cyclophosphamide for severe AAV with high-sustained remission rates in both groups. Rituximab-based therapy was not associated with reductions in early adverse events. However, rates of cardiovascular disease and malignancy in AAV increased, as well as, underlying patterns of disease such as accelerated atherosclerosis [55] raising other concerns that there might be non-traditional risk factors such as endothelial activation and excessive vascular remodeling [56]. Early outcome results for the treatment of childhood AAV, in particular GPA, reported by Morishita and colleagues on behalf of ARCHiVe Investigators Network and the PedVas [57] have been less encouraging than in adults. Among 105 children with AAV, mainly GPA, who received CS, CYC, MTX, or RTX for remission-induction, and PE in conjunction with CYC and/or RTX, 42% achieved remission at 12 months (Pediatric Vasculitis Activity Score [PVAS] of 0, CS dose < 0.2 mg/kg/day), 21 (48%) of whom discontinued corticosteroids by 12 months; all but 3 remaining on maintenance treatment at 12 months receiving azathioprine, methotrexate, rituximab, mycophenolate mofetil, and cyclophosphamide. However, up to 63% had a Pediatric Vasculitis Damage Index [PVDI]

score of 1 or more by 12 months, with the presence of renal, ear, nose and throat, or pulmonary damage; and 41% of children reported hospitalizations. Thus, a significant proportion of patients were not in remission at 12 months, and more than one-half of the patient cohort experienced damage early in the disease course. The 12-month remission rate of 42% in the cohort was significantly lower than Sacri and colleagues [58], who reported 73% remission at post-induction and 90% overall remission rate (including secondary remissions after a median time of 6.7 months). Disappointing early outcomes in the PedVas treatment study for GPA [57] serve as a cautionary note in the treatment of IBrainD and cPACNS with similar immunosuppressive regimens.

Fifth, animal models of AAV [59] have enabled the transfer of murine MPO-ANCA IgG without functioning B-, or T-cells, resulting in pauci-immune, necrotizing crescentic glomerulonephritis similar to human AAV [60, 61], while other lines of evidence link infection to ANCA-related autoimmunity through molecular mimicry [62]. Using experimental material from patients with inflammatory vascular disease caused by ANCA and specificity for PR-3, autoimmunity can be initiated through an immune response against a peptide, antisense or complementary to the autoantigen, which then induces anti-idiotypic antibodies cross-reactive with the autoantigen [63].

Table 1. Recommendations for the treatment of vasculitides

<i>Large Vessel Vasculitis</i> GCA, TAK: CS, AZA, RTX, infliximab, anti-TNF α , anti-IL-6R, tocilizumab, and MM. Adjunctive therapy: ASA and AC.
<i>Medium Vessel Vasculitis</i> PAN, KD: CS and CYC; MM.
<i>Small Vessel Vasculitis-AAV Type</i> GPA, EGPA, MPA: Induction with CS + CYC; CS + RTX; or CS + MM and maintenance RTX, AZA or MM.
<i>Small Vessel Vasculitis- IC Type</i> CV: MM; INF-alpha and PegINF-alpha plus ribovarin or RTX in HCV-associated MC. IgAV: CS and/or MM; and supportive care.
<i>Hypocomplementic-C1q</i> : Antihistamines, IVIg, PE.
<i>Variable Vessel Vasculitis</i> Cogan Syndrome: CS. BD: CS, MM; colchicine or anti-TNF α .
<i>Single Organ Vasculitis-Isolated Aortitis, PACNS</i> Isolated Aortitis: CS, AZA, MM, MTX. cPACNS: Induction with CS, CS +CYC or RTX, followed by maintenance with AZA, MTX or MM PCNSV: Induction with CS, CS +CYC or RTX, followed by maintenance with AZA, MTX or MM
<i>Vasculitis Associated With Systemic Collagen Vascular Disease-SLE, RAV</i> SLE: CS, MM; and AC. RAV: CS, RTX, infliximab and AZA or MTX
<i>Vasculitis Associated with Illicit Substance Abuse</i> Avoid illicit substance.
<i>Vasculitis Associated with Infection</i> Antimicrobial agents chosen specifically to treat a given etiologic organism.

Abbreviations: AC, anticoagulation; ASA, aspirin; AZA, azathioprine; BD, Behçet disease; CS, corticosteroids, CV, cryoglobulinemic vasculitis; CYC, cyclophosphamide; EGPA, eosinophilic granulomatosis with polyangiitis; GCA, giant cell arteritis; GPA, granulomatosis with polyangiitis; HCV, hepatitis C virus; IC, Immune complex; IgAV, IgA vasculitis; INF, interferon; IL, interleukin; IVIg, intravenous immune globulin; KD, Kawasaki disease; MC, mixed cryoglobulinemia; MM, mycophenolate mofetil; MPA, microscopic polyangiitis; MTX, methotrexate; cPACNS, childhood primary angiitis of the central nervous system; PCNSV, primary central nervous system vasculitis; PAN, polyarteritis nodosa; PE, plasma exchange; RAV, rheumatoid arthritis vasculitis; RTX, rituximab; SLE, systemic lupus erythematosus; TAK, Takayasu arteritis; TNF, tumor necrosis factor.

Sixth, there is increasing evidence for the role of both humoral-mediated and cell-mediated immunity in AAV, with involvement of complement activation in the renal damage of human ANCA-associated pauci-immune vasculitis [64]. Cell-mediated immunity is exemplified by activation of circulating T-cells and B-cells, with infiltration of plasmoblasts into affected tissues [65] are co-stimulated by the secretion of pro-inflammatory cytokines including IL-6 and TNF α . While T-cells contribute an important role in the pathogenesis of AAV [66], B-cells are still the main therapeutic target as precursors of ANCA-secreting plasma cells.

CONCLUSION

The heterogeneous nature of the systemic vasculitides expresses itself in the diversity of clinical presentations. The diagnosis rests upon first considering it as a possibility based upon the history and physical examination and supportive findings thereof on laboratory studies. Accurately diagnosed and so treated, the outcome can be favorable.

ABSTRACT

Polyarteritis nodosa is an exemplary multi-systemic medium-sized, primary systemic vasculitis of adults and children. Once the most frequent vasculitis, it has become progressively less common notably in developed countries due to eradication of hepatitis B virus infection, one of its most frequent causes. The evolution of clinical manifestations commences with the acute phase of neutrophilic and variable lymphocytic and eosinophilic inflammation of arterial vessel walls with medial necrosis, followed by aneurysm formation, and later by the healing of lesions that entrains fibrotic endarteritis and vascular occlusions. The coexistence of necrotizing vasculitis, healed lesions and normal arteries in different tissues or portions of the same tissue is a pathognomonic feature of the disease. Effective treatment of polyarteritis nodosa, which includes consideration of corticosteroids and cyclophosphamide depending upon the presence of favorable or unfavorable prognostic factors, and an antiviral agent if complicated by hepatitis B infection, have improved the 5-year survival of patients. This chapter considers aspects of the classification criteria, epidemiology, etiopathogenesis, main clinicopathologic features, treatment and outcome of PAN.

Keywords: polyarteritis nodosa, vasculitis, CNS, PNS, systemic vasculitis

INTRODUCTION

In 1852, Carl von Rokitansky, Professor of Pathology at the University of Vienna described polyarteritis nodosa (PAN) in a 23-year-old man with a 5-day history of fever and diarrhea [1]; Küssmaul and Maier [2] rediscovered the disorder in 1866. Within decades, PAN was one of the most frequent vasculitides which became progressively less common in developed countries as a consequence of the eradication and treatment of one of its most frequent causes [3], hepatitis B virus (HBV) infection. This chapter reviews the classification criteria, epidemiology, etiopathogenesis, main clinicopathologic features, treatment and outcome of PAN.

CLASSIFICATION AND DIAGNOSTIC CRITERIA

In 1990, the American College of Rheumatology (ACR) (Table 1) established criteria for the classification of PAN [4], and although frequently cited, it did not distinguish between PAN and microscopic polyangiitis (MPA). These two disorders were initially considered different forms of the same disease because of similar main clinical manifestations. However, the two entities were clearly distinguished by the 2012 Revised Chapel Hill Consensus Conference (CHCC) Nomenclature [5], defining PAN as a necrotizing arteritis of medium- or small-sized arteries without glomerulonephritis, vasculitis in arterioles, capillaries or venules; and absent anti-neutrophil cytoplasm antibodies (ANCA). While both disorders involve the kidneys such as glomerulonephritis in MPA and vascular nephropathy in PAN, the former is associated with lung capillaritis while the latter has at most subclinical lung involvement. Moreover, the two disorders may be difficult to discern when nephropathy and lung capillaritis are absent, and especially when tissue biopsy does not distinguish involved vessel types or size. The 2012 Revised CHCC Nomenclature classifies PAN in the category of medium-sized vessel vasculitis (MVV), and vasculitis associated with a probable etiology when associated with HBV infection. ANCA serology, so noted in the majority of patients with MPA and other small-sized-vessel vasculitides (SVV) including granulomatosis with polyangiitis (GPA) and eosinophilic granulomatosis with polyangiitis (EGPA), is virtually never detected in PAN. Accordingly, a positive ANCA serology excludes the diagnosis in a given patient. It is important to emphasize that the Chapel Hill Consensus defined the nosology of vasculitides, but not the diagnostic criteria. Given that the 1990 ACR criteria are misleading, internationally recognized criteria are needed. Table 2 lists criteria useful in the diagnosis of PAN [6].

EPIDEMIOLOGY

PAN affects all racial and ethnic groups with an estimated annual incidence in the general population from 4.6 per 1,000,000 inhabitants in England [7], to 9.0 per 1,000,000 inhabitants in Olmsted County, Minnesota, to 77 per 1,000,000 inhabitants in a hepatitis B-hyperendemic Alaskan Eskimo population [8]. In a German study [9], the incidence of PAN was 0.3 to 0.4 per 1,000,000 inhabitants depending on the year and part of the country. A comparison of the

incidence of PAN among two European areas of Lugo, Spain, and Norwich, United Kingdom (UK) found insignificant incidence differences of 6.2 and 9.7 and 1,000,000 inhabitants [10, 11]. In France, the prevalence of PAN was 34 per 1,000,000 inhabitants in Seine–Saint-Denis, a northern suburb of Paris [12].

Table 1. 1990 ACR criteria for the classification of polyarteritis nodosa*

Criterion	Definition**
1. Weight loss >4 kg	Loss of ≥ 4 kg of body weight since illness began, not due to dieting or other factors
2. Livedo reticularis	Mottled reticular pattern over the skin of portions of the extremities or torso
3. Testicular pain or tenderness	Pain or tenderness of the testicles, not due to infection, trauma or other causes
4. Myalgia, weakness, or leg tenderness	Diffuse myalgia (excluding shoulder and hip girdles), or weakness of muscles or tenderness of leg muscles
5. Mononeuropathy or polyneuropathy	Development of mononeuropathy, mononeuropathy multiplex, or polyneuropathy
6. Diastolic BP > 90 mm Hg	Development of hypertension with the diastolic BP > 90 mm Hg
7. Elevated BUN or creatinine	Elevation of BUN > 40 mg/dL (14.3 mmol/L) or creatinine >1.5 mg/dL (132 μ mol/L), not due to dehydration or obstruction
8. Hepatitis B virus	Presence of hepatitis B surface antigen or antibodies in serum
9. Arteriographic abnormality	Arteriogram showing microaneurysms or occlusions of the visceral arteries, not due to arteriosclerosis, fibromuscular dysplasia or non-inflammatory causes
10. Biopsy of small- or medium-sized artery containing neutrophils	Histological changes showing the presence of granulocytes or granulocytes and mononuclear leukocytes in the artery wall

* Adapted from, reference [4].

** For classification purposes, a patient with vasculitis shall be said to have PAN if at least 3 of these 10 criteria are present. The presence of any 3 or more criteria yields a sensitivity of 82.2% and a specificity of 86.6%.

Abbreviations: ACR, American College of Rheumatology; BP, blood pressure; BUN, blood urea nitrogen; kg, kilogram; mmHg, millimeters of mercury.

Table 2. Diagnostic criteria for adult-onset polyarteritis nodosa*

Criteria**	OR	95% CI	R ²
Positive for PAN			
HBV infection	16.85	6.30–45.08	0.320
Myalgia	1.93	1.06–3.53	0.517
Mononeuropathy or polyneuropathy	3.36	1.93–5.86	0.619
Arteriographic abnormalities	20.40	7.30–56.99	0.640
Testicular pain or tenderness	5.27	1.98–28.26	0.661
Negative (exclusion) for PAN			
ANCA-positivity	0.11	0.05–0.23	0.668
Glomerulonephritis	0.07	0.02–0.29	0.674
Recent asthma onset	0.01	0.01–0.06	0.433

* Adapted from reference [6].

**Based on the analysis of 582 systemic vasculitis patients with all data available in the French Vasculitis Study Group's database: 194 PAN (among whom 117 had HBV-related PAN) and 388 other systemic vasculitides (GPA, n = 144; EGPA, n = 115; MPA, n = 101; cryoglobulinemia, n = 28). Abbreviations: OR, odds ratio; CI, confidence interval; R, coefficient of determination.

The incidence of PAN has dramatically declined in parallel with HBV infection [3], and is now very rare indeed. Public health measures including vaccine prophylaxis, blood-transfusion safety and other prophylactic measures against infectious exposure have resulted in the sharp drop in the annual number of PAN cases, suggesting a contributory infectious etiopathogenesis. Although HBV infection is a known cause of PAN, other infectious agents including viruses may be implicated in its onset. Although incidence of PAN has significantly decreased, paralleling HBV infection control, the incidence of PAN not related to HBV seems to increase again in France.

PATHOGENESIS

The immunopathogenic mechanisms leading to vascular injury in PAN are likely heterogeneous and remain largely unexplained. Vascular inflammation is the consequence of immune-complex (IC) mediated lesions [13–15]. When HBV infection causes PAN, evidence supports IC disease with HBV surface antigen (HBsAg) as the triggering factor [16, 17]. Almost all patients with HBV-related-PAN are associated with wild-type HBV, HBe antigenemia and high HBV replication, bolstering the concept that lesions could result from the deposition of soluble HBV antigen–antibody complexes in antigen excess, possibly involving HBeAg. Immune complexes could activate the complement cascade, the activated components of which could in turn attract and stimulate neutrophils. Circulating HBV-related antigens, distinct from HBeAg may be involved, as could direct endothelial cell injury due to viral replication [18]. Anti-endothelial cell autoantibodies (AECA), directed against antigens expressed on the endothelial cell surface, have been implicated as a pathogenic factor participating in vasculitis [19] leading to direct endothelial damage. There is yet little known of the possible vasculitic target autoantigens and whether AECA are of pathogenic significance. However, the sera of some patients with PAN and AECA recognize a 60-kDa heat-shock protein [20, 21]. Markedly increased interferon (IFN)- α and interleukin (IL)-2 levels, and moderately elevated tumor necrosis factor (TNF)- α and IL-1 β levels were detected in the sera of patients with PAN [22]. Inflammatory infiltrates, mainly macrophages and T-cells, particularly of CD8⁺ subset, were observed in perineural and muscle vessels of patients with PAN [23]. T-cell-mediated immune mechanisms likely play a role in the development and perpetuation of PAN lesions however to date there have been no experimental animal models. A PAN-like disorder in *cynomolgus* macaques [24, 25] very similar to the human disease sporadically occurs.

ETIOLOGY AND PRECIPITATING FACTORS

Relation to HBV Infection

Trepo and colleagues [16, 26] described the close relation between PAN and HBs antigenemia. In 1987 Guillevin and colleagues [3] reported one of the first addict patients who were proven to be contaminated by intravenous drugs. Intravenous drug abuse and sexual transmission of HBV to at risk, non-vaccinated individuals are the major causes of

HBV-related PAN. The development and distribution of anti-HBV vaccines to at-risk individuals explains the dramatic decrease in the number of new cases since 1989. Over the past few years, the frequency of HBV-related PAN has progressively declined and almost disappeared. Indeed, for the last 5 years, fewer than five cases have been identified annually throughout France.

Other Etiologies

In spite of occasional anecdotal cases [27], neither hepatitis C (HCV) nor GB virus, the latter phylogenetically related to the former were considered etiologically important in the development of PAN. Although there were several reported patients with parvovirus B19-infection [28], systematic testing of PAN patients did not find their occurrence to be statistically significant compared to controls [29]. Calabrese [30], and Gisselbrecht and colleagues [31] suggested a role for human immunodeficiency virus type 1 (HIV1) in the development of vasculitis. A close relation between hairy-cell leukemia and PAN was suggested by Elkon and colleagues [32, 33], but the relation to other malignancies has not been apparent. A Cleveland Clinic Foundation retrospective study by Hutson and coworkers [34] reported 69 patients with systemic vasculitis and malignancy, twelve of whom had both diseases occurring in same twelve months period, including two with PAN.

In 2014 a new monogenic autoinflammatory disease has been characterized, with many clinical and pathological features corresponding to hallmarks of PAN [35, 36]. The newly named DADA2 (Deficiency in Adenosine DeAminase 2) corresponds to a loss-of-function mutation in the CECR1 gene (Cat Eye syndrome Chromosome region 1). Although the role of ADA2 protein as a growth and differentiation factor for monocytes is known, the underlying pathophysiological mechanisms of the disease remain unclear. Children may present with necrotizing vasculitis, mimicking PAN, with strokes and hypogammaglobulinemia. Nevertheless, adult-onset cases have been reported and clinicians should be aware of this misleading disease for which new mutations have been described recently [37, 38]. DADA2 could be considered as a differential diagnosis for patients diagnosed as PAN if they have a family history of vasculitides, early stroke, an immune deficiency, or fail to respond to conventional therapy. Indeed, conventional immunosuppression is frequently ineffective while TNF- α blockers show interesting results [37, 39, 40].

We recommend CECR1 screening for unaffected siblings of index cases, cases of familial vasculitis, and cases of PAN that is resistant to standard treatment. Indeed, ADA2 deficiency could be a differential diagnosis of PAN or one of its cause. The phenotypic expression of PAN is common to infectious or non-infectious disease and shows that PAN could be a heterogeneous disease, due to different etiologies or pathogenic mechanisms. It may be that the individualization of ADA2 deficiency is one of the steps in deciphering PAN.

PATHOLOGY

PAN lesions can occur in any artery, but involvement of the aorta, other large elastic arteries and the pulmonary vasculature have rarely been described. The acute phase of arterial

wall inflammation is characterized by fibrinoid necrosis of the media and intense pleomorphic cell infiltration, with predominant neutrophil and variable lymphocytic and eosinophilic inflammatory cells. The normal architecture of the vessel wall, including the elastic lamina, is completely destroyed and replaced by a band of amorphous eosinophilic material that resembles fibrin when appropriately stained. Arterial aneurysms and thromboses can occur at lesion sites. Arterial healing is characterized by fibrotic endarteritis that can lead to aneurysm regression or when too abundant, vascular occlusion. A characteristic histological feature of PAN is the coexistence of necrotizing vasculitis and healed lesions or normal arteries in different tissues or in portions of the same tissue sample. Indeed, the lesions are usually segmental with presence of damages of different ages.

SPECIFIC ORGAN SYSTEM MANIFESTATIONS

Clinical Features

Table 3 shows the main clinical manifestations of PAN. This disorder occurs in patients of all ages, including children and the elderly, albeit most often between the ages of 40 and 60 years, without sexual predominance. A poor general condition is common, with two-thirds of patients experiencing weight loss and fever. Non-specific symptoms which occur early in the course of disease may be present at onset or even the singular manifestation. Although PAN is most often diagnosed after systemic manifestations appear, it is important to consider the diagnosis among individuals with unexplained or prolonged poor general health.

Table 3. Main organ or system involvement and clinical manifestations of polyarteritis nodosa in the literature

Reference	Patients (n)	Mean age	Organ/system involved or manifestation (%)

*These older studies may have included PAN patients who would now be diagnosed as having MPA. Abbreviations: CNS, central nervous system; GI, gastrointestinal; PNS, peripheral nervous system.

Figure 1. Peroneus muscle hyperintense signals on T₂-weighted MRI in a PAN patient with skeletal muscle involvement.

Myalgia and Arthralgia

Up to one-half of patients have variably intense, diffuse and spontaneous myalgia, with normal or slightly elevated muscle enzyme levels. Amyotrophy may be marked reflecting weight loss sometimes exceeding 20 kilograms (kg), or underlying peripheral neuropathy. Affected patients may be bedridden due to pain severity and amyotrophy. Magnetic resonance imaging (MRI) of painful muscles can show hyperintense signal intensities on T₂-weighted enhanced images after administration of gadolinium (Figure 1) due to inflammatory lesions. Skeletal muscle MRI, which correlates poorly with the presence of vasculitis, is not recommended in the selection of the site for muscle biopsy. Rather, the biopsy should be performed distally in an affected limb especially in painful areas to maximize pathogenic vasculitic lesions which may be in differing stages of evolution. Arthralgia occurs in the knees, ankles, elbows and wrists, rather in the shoulders or hips; arthritis is typically absent and joint deformities do not occur.

NERVOUS SYSTEM INVOLVEMENT

Peripheral Neuropathy

Peripheral neuropathy is the most common peripheral nervous system (PNS) manifestation, so noted in up to 75% of affected patients [41, 48], and may be the earliest symptom in up to a third. Segmental edema precedes the development of cranial nerve palsy reflecting capillary-permeability dysfunction. Hypo- and hyperesthesia, dysesthesia and frank pain, resulting from sensory nerve involvement, are prominent and earliest presenting complaints. Motor deficits typically affect the legs often preceding sensory involvement, commencing suddenly with involvement of one nerve at a time, termed mononeuritis or

mononeuropathy multiplex, in one-half to two-thirds of patients [41, 51]. The peripheral neuropathy is typically distal and asymmetric, preferentially affecting the fibular, sural, radial, ulnar, and median nerves. A symmetrical process may be observed due to the coalescence of nerve lesions. Cerebrospinal fluid (CSF) findings are typically normal and electromyography (EMG) and nerve conduction studies (NCS) are compatible with an axonopathy process evidenced by reduced compound muscle action potential (CMAP) amplitudes with normal or near normal conduction velocities. Rare patients are encountered with brachial plexus neuropathy [52] and peripheral motor conduction block [53] indicative of a demyelinating process similar to Guillain–Barré syndrome or other acquired demyelinating neuropathies, and peripheral nerve entrapment [54]. Isolated sensory neuropathy is a rare complication of PAN and may be the consequence of isolated small fiber involvement vasculitis [55]. Mononeuropathy multiplex regresses slowly and improves to a variable degree in over 12 to 18 months following effective therapy without residual lesions, however paresthesia can persist longer or indefinitely.

Isolated peripheral nerve vasculitis, categorized as a single organ vasculitis (SOV) [56] by the 2012 Revised CHCC Nomenclature [5], differs from the isolated phenotypic expression of PAN that often conveys a more benign and chronic outcome.

Central Nervous System Manifestations

Central nervous system (CNS) involvement was observed in 4.6% of patients with PAN [41]. Affected patients with encephalopathy have altered cognitive function with disorientation, psychosis, hallucinations. There can be focal or multifocal neurological disturbances leading to seizures, strokes or subarachnoid hemorrhages [57] resulting from focal cerebral arteritis leading to cerebral artery-aneurysm rupture and hematoma, alternatively due to malignant hypertension. Distal occlusion of spinal vessels engenders sphincter dysfunction [58]. MRI of the brain typically shows non-specific T₂-weighted white matter subcortical hyperintensities, while MR angiography (MRA) and conventional cerebral angiography may be normal.

Cranial Nerve Manifestations

Albeit rare, involvement of the oculomotor, trochlear, abducens, facial, and vestibulocochlear nerves are most often affected in PAN [59]. Effective treatment can lead to partial or full recovery, which is less likely in the vestibulocochlear nerve [60]. There may be vasculitis of the optic nerve, optic chiasm or occipital cortex. Cerebrospinal fluid is typically normal.

Dermatologic Manifestations

Despite involvement of medium-sized vessels, one-half of patients with systemic PAN have cutaneous lesions [41] including cutaneous and subcutaneous nodules, and palpable

purpura, which can be bullous or necrotic (Figure 2). Skin nodules occur in clusters along the trajectories of superficial arteries, often disappearing spontaneously over a few days prior to new lesions. Palpable nodules can reach a size of 20 mm. Skin ulcerations and livedo reticularis occur less frequently [47]. The latter is typically localized to the legs, the backs of the arms, and sometimes the trunk with a fish net reticular pattern of infiltrated areas. Painful distal ulcerations may be associated with ischemia of the fingers and toes, and distal gangrene. Digital ischemia should lead to consideration of cholesterol and atherosclerotic emboli. Angiography demonstrates vascular stenosis or microaneurysm formation [61].

Figure 2. Necrotic purpura in the legs and ankles of a patient with PAN.

PAN may be limited to the skin for decades before development of systemic vasculitis, without systemic involvement, abnormal biological markers of inflammation or circulating autoantibodies [62, 63]. Skin relapses are not uncommon.

Renal Manifestations

Renal manifestations result from medium-sized-vessel involvement leading to renal infarcts and microaneurysm formation. Malignant arterial hypertension [64], which occurs in 6.9% of patients [41], reflects vascular ischemic nephropathy. Renal insufficiency is an overall poor prognostic factor [65]. Angiography shows renal parenchymal infarction (Figure 3), with characteristic multiple stenosis and microaneurysms of branches of celiac, mesenteric and renal arteries (Figure 4). Microaneurysms can spontaneously rupture notably after renal biopsy, the latter of which is strongly contraindicated when microaneurysms are present. Renal hematoma can be extensive requiring embolization [66] or nephrectomy [67]. Acute renal insufficiency can occur soon after onset or following a disease flare. Plasma exchanges may be required initially however renal function is unpredictable. Some patients develop end-stage renal failure decades after the first PAN flare.

Figure 3. Renal infarcts reflecting vascular nephropathy.

Figure 4. Multiple renal artery microaneurysms.

Cardiac Manifestations

Cardiac involvement was mentioned in the first publication of PAN [2] that described a patient with “nodular coronaritis”. Clinical cardiac involvement occurs in 10% of patients with clinical expression of PAN [48], with an increase to 40% after recognition of radiologic and electrocardiographic abnormalities, and in 78% of those studied histopathologically [68]. Although one recent series [41] found cardiac involvement in 22.4% of patients with PAN, this frequency may have underestimated the true occurrence since newer laboratory investigations were not employed to gauge cardiac involvement. Congestive heart failure, the main clinical manifestation of cardiac involvement, reflects both vasculitis of the coronary arteries and its branches with myocardial arteriolar infarcts, and end-organ renovascular or hypertensive disease.

Cardiomyopathy occurs 3 to 4 months after onset of PAN onset. Despite coronary artery vasculitis, angina and myocardial infarctions are uncommon. Among 66 postmortem studied patients, 41 had features of myocardial infarction, of whom three had clinical cardiac symptoms, and three had coronary atherosclerosis [68]. Coronary angiography and CT of the coronary arteries demonstrate coronary involvement in most affected patients with clinical signs of myocardial infarction, and in some, the latter be a result of small coronary artery vessel vasculitis or vasospasm [69]. Coronary artery aneurysm, notably in children, suggests Kawasaki disease (KD), however rupture of them is uncommon but severe, because it can cause a hemopericardium.

There are no current guidelines for the evaluation of coronary artery involvement in PAN, however cardiac MRI may be promising. Heart murmurs are generally due to anemia and not endocardial involvement, the latter of which is infrequent in PAN such that its presence should lead to an alternative diagnosis. Even less common non-specific pericardial manifestations reflect secondary myocardial involvement so noted in up to 5% of patients with PAN [70]; a frequency that increased to one-third in postmortem series [68]. Supraventricular cardiac arrhythmia and conduction disorders occur in 2 to 19% of PAN patients [68, 71] due to arteritis of the sinus node and neighboring nerve fibers.

Aortic Dissection and Peripheral Vascular Manifestations

These authors have not observed a case of PAN-related aortic dissection, a rare complication that is attributed to diffuse vasculitis of the vasa vasorum which manifested in one such case as fatal tamponade [72]. Dissection of proximal aortic branches and Raynaud phenomenon when present may be complicated by vasonecrosis. Cryoglobulinemia may be found in patients with cardiac disease and HBV-related PAN.

Gastrointestinal Manifestations

Gastrointestinal manifestations are among the most severe in PAN, affecting 38% of patients [41], most often associated with HBV infection, so noted respectively in 50.4% versus 31.1% of patients. While generally reflective of systemic involvement, they may also

be the initial findings of PAN [3]. Gastrointestinal complications are a major cause of death in the first year of disease ranking third after infection and cardiac disease [73]. Abdominal pain was the most common symptom, so noted in 30 to 40% of patients with PAN and overall in 97% of those with gastrointestinal involvement. The intensity and persistence of abdominal pain despite corticosteroids treatment, suggests a vascular cause and confer a less favorable prognosis [74]. Hemorrhage and small intestine perforation are the most feared manifestations with respective reported frequencies of 20% to 50% and 2% to 40% (mean, 5%) [75]. When present, ischemic vasculitis affects the small bowel and more rarely the colon and stomach. Perforation of the esophagus is unusual; and vasculitis of the gallbladder occurs in 2% to 17% of patients [75–77].

Vasculitic appendicitis may be the first manifestation of PAN or a localized form thereof. Patients with isolated and histologically-proven vasculitic appendicitis progress to systemic PAN within five years. The prognosis of closely monitored and surgically treated necrotizing vasculitis of the gallbladder or appendix is generally favorable without immunosuppressant treatment. Acute necrotizing and chronic pancreatitis, the latter often accompanied by pseudocyst formation, were diagnosed in 3.7% of patients [41], however the prognosis is extremely dismal because of the frequent association with small intestinal ischemia and perforation. Exploratory surgery should be performed in such patients to detect underdiagnosed bowel perforation. Digestive malabsorption and exudative enteropathy rarely occurs. The liver and spleen can be involved with or without hematoma formation [78] that may be clinically silent. One patient with fibrinoid necrosis of the splenic artery and later splenic rupture was described [45]. When abdominal pain is present, computed tomography (CT) and MRI of the abdomen can be useful to detect organ infarction and pancreatitis. Gastric and colonic endoscopy can detect areas of ischemia and ulceration that precede perforation. Of note, despite increasing resolution performance of CT and MRI imaging, angiography remains the gold standard to detect microaneurysms.

Angiography, which images areas of organ infarction, hematoma and microaneurysm formation measuring 5 mm in diameter, identifies suggestive areas of arterial stenosis in up to 90% of patients with PAN. Angiography also depicts vascular lesions in renal, celiac, and mesenteric vessels respectively in 54%, 24%, and 14% of patients, although even more often in hepatic and splenic arteries [41, 79] without prognostic significance. While not rapidly fatal, intraperitoneal ruptures of such aneurysms are treatable with selective arterial embolization. Gastrointestinal tissue biopsy, i.e., during GI tract endoscopy or liver fine needle biopsy, rarely detects vasculitis and may be life-threatening with a risk of aneurysm rupture. However, histologic examination of whole organ after surgery is of outmost importance as it regularly confirms diagnosis.

Severe GI manifestations, like bowel perforations and ischemia, peritonitis and intestinal occlusion, confer a poor prognosis [65]. Effective treatment combines prompt surgical intervention and medical therapy with corticosteroid and immunosuppressive treatment.

Testicular Manifestations

Unilateral orchitis and testicular tenderness due to testicular artery ischemia were common findings in PAN, so noted in 17% of patients, although rarely the first manifestation of disease [41, 80]. Indeed, orchitis was included in the 1990 ACR classification criteria of

PAN [4]; and although it typically improves with a prompt course of corticosteroids, however in some instances it can be irreversible. We noted orchitis in association with HBV-related PAN however an etiologic relation between viral infection and testicular manifestations was not discerned [3]. Fertility is usually preserved.

Ureteral and Urogenital Manifestations

Ureteral manifestations are rare and ureteral stenoses are specific of small-sized-vessel vasculitis SVV. Urodynamic and electrophysiological studies may demonstrate detrusor hypoactivity in patients with voiding difficulty when the cause is vasculitis of vasa nervorum supplying the bladder. It is unusual to discern a vasculitic spinal cord etiology for bladder disturbances.

Pulmonary Manifestations

Unlike MPA, GPA and EGPA, pulmonary involvement in PAN is either asymptomatic or subclinical, even when histopathologic involvement is found at postmortem examination. Size of involved vessels in PAN explains the absence of lung manifestations as only bronchial arteries are medium-sized vessels and parenchymal vessels are exclusively small-sized arterioles, capillaries and venules.

Bone Manifestations

Periosteal involvement resulting from pan develops mainly in the legs (Figure 5) with associated pain and localized edema, tissue biopsy of which may reveal underlying necrotizing vasculitis [81, 82].

Figure 5. Fibula periostitis during PAN illustrated on X-rays radiograph and nuclear imaging, adapted from [82].

Ophthalmologic Manifestations

Ocular manifestations of necrotizing vasculitis were noted in 42/393 (10.7%) of patients with PAN [83] the most common features of which included blurred vision in 31%, sudden visual loss in 19%, retinal vasculitis in 16.7%, and uveitis in 11.9% of patients. Conversely to AAV, scleritis, episcleritis and other manifestations are rarely observed.

HBV-RELATED MANIFESTATIONS

An onset before age 40 years, concomitant malignant hypertension, renal infarction, orchi-epididymitis, gastrointestinal manifestations, and surgical emergencies were all more frequent in HBV-associated infection. Sergent and coworkers [84] noted that two of the three deaths among nine patients were attributed to colon vasculitis. Ischemia was responsible for gastrointestinal and renal manifestations that were due to microaneurysm formation and infarction noted on visceral angiography. Effectively treated, microaneurysms regress on serial angiography [85] that may result from microaneurysmal thrombosis with evolution to fibrosis. Hepatic cytolysis is usually moderate and cholestasis is minor or absent. Liver biopsy pathology exhibits signs of chronic hepatitis even when PAN becomes manifest a few months after HBV infection. HBV-related PAN is acute and initially severe but the outcome is excellent for most patients when adequate treatment is associated with seroconversion. The sequela of vascular nephropathy is similarly favorable in those patients able to obtain substantial recovery with little residual functional renal impairment.

CHILDHOOD PAN

PAN is the most common systemic necrotizing vasculitis in children after KD and IgA vasculitis (Henoch–Schönlein purpura or HSP) [86]. Neither the ACR criteria [4] nor the 2012 Revised CHCC Nomenclature [5] were validated for children. The European League against Rheumatism/Pediatric Rheumatology European Society (EULAR/PReS) proposed specific classification criteria for juvenile vasculitides [87].

The EULAR/PReS criteria [87] were based mainly on a literature review and a consensus-based process. The primary objective of the 2008 Ankara Consensus Conference was to validate the EULAR criteria for pediatric vasculitides. The final EULAR/PRINTO/PReS childhood PAN (cPAN) classification criteria achieved a sensitivity of 89.6% and a specificity of 99.6% and are indicated in Table 4 [88]. Since their setting, several case-series used these criteria [50, 89]. In the work from the French Vasculitis Study Group's database, among 21 cPAN patients 86% met the criteria [50].

The mean age at diagnosis of childhood PAN is age 9 ± 4 years, with an equal ratio of boys and girls. Clinical manifestations fall within the same spectrum as for adults, except for more frequent cutaneous involvement in children. Indeed, 80% of affected children manifest skin involvement, with a limited cutaneous form accounting for one-third of cases. Prognosis is more favorable for children than adults with an overall mortality rate of 1% to 16%. Relapses are more frequent and occur only many years following diagnosis, sometimes

preceded by ear, nose and throat infections. Penicillin can contribute to a cure by effectively lowering the relapse rate when *Streptococci* are involved as the cause or target factor [90]; however, the optimal antibiotic regimen is unknown. Relapses have been described up to 20 years after the first episode.

Table 4. EULAR/PRINTO/PReS proposed classification criteria for childhood polyarteritis nodosa*

A systemic inflammatory illness characterized by the presence of
-At least 1 mandatory criterion:
1. Biopsy showing small- and medium-sized artery necrotizing vasculitis
2. Angiographic abnormalities on medium or small-sized arteries: aneurysms, stenoses or occlusions [†]
-Plus 1 among the 5 clinical criteria:
1. Skin involvement: livedo reticularis, skin nodules, superficial or deep skin infarctions
2. Myalgia or muscle tenderness
3. Systemic hypertension, greater than 95 th percentile for the age
4. Peripheral neuropathy: mononeuropathy or polyneuropathy
5. Renal involvement: abnormal urine analysis (proteinuria >0.3 g/24h or hematuria) and/or impaired renal function with GFR < 50% of normal

* Adapted from reference [88] [†]Should include angiography if MR angiography is negative. Abbreviations: EULAR/PRINTO/PReS, European League against Rheumatism/Pediatric Rheumatology Inter National Trials Organization/Pediatric Rheumatology European Society; GFR, glomerular filtration rate.

LABORATORY EVALUATION

Inflammation markers are found in the majority of patients. A one-hour erythrocyte sedimentation rate (ESR) >60 mm is noted in three-quarters of patients; and an elevated C-reactive protein, α -2 globulin levels and white blood-cell counts in one-half to three-quarters of patients. Eosinophilia >1,500/mm³ and normochromic anemia can occur. HBsAg and ANCA serology should be routinely tested.

As previously described, the DADA2 syndrome can mimic PAN, therefore genetic testing should be performed for the following: childhood-PAN-like presentation with familial history of vasculitis or early stroke for the patient, unresponsiveness to standard therapy protocols.

IMAGING

Bron and coworkers [91] showed the diagnostic value of angiography in visualizing saccular or fusiform microaneurysms measuring 1 to 5 mm in diameter, and stenosis in medium-sized vessels. Although not pathognomonic for PAN, they are predominantly seen in the kidneys, mesentery and liver. Angiography is a useful tool when other diagnostic examinations are negative, especially when abdominal pain and nephropathy are present. As cited for HBV-related PAN, the microaneurysms may disappear after several months with the resolution of the causative agent [85].

Of note, despite increasing resolution performance of CT and MRI imaging, angiography remains the gold standard to detect microaneurysms as these technics currently fail to detect

such aneurysms in all cases [92]. Nonetheless, it is likely that in the future invasive angiography is abandoned thanks to imaging progress.

Unlike large-vessel vasculitides, PET/CT scan usage as a diagnosis tool appears limited in PAN, mainly due to the smaller size of affected vessel. Nonetheless its positivity has seldom been reported as localized [93] or diffuse [94] 18-FDG uptake. Therefore PET/CT is not routinely recommended for PAN diagnosis or follow-up.

PROGNOSIS AND OUTCOMES

Untreated, 12% of patients with PAN survived [48]. However, with effective therapy the overall survival rate exceeded 80% [95] for PAN alone, and 70% in those with associated HBV infection [3]. A systematic retrospective study of 348 patients with PAN registered in the French Vasculitis Study Group (FVSG) database [41] satisfying ACR [4] and CHCC Nomenclature [5], and followed for 68.3 months showed relapses in 76 (21.8%) and deaths in 86 (24.7%). Mortality and relapse rate were significantly different between PAN groups with and without HBV infection. HBV infection appears associated to higher mortality but lower relapses rates. Indeed, 44 patients died (19.6%) with PAN alone versus 42 (34.1%) with associated HBV infection ($P = 0.003$). Regarding relapses, 63 (28%) relapsed with PAN alone versus 13 (10.6%) with associated HBV infection ($P < 0.001$) and the 5-year relapse-free survival rate for PAN was 59.4% (95% confidence interval [CI] 52.6–67.0) versus 67.0% (95% CI 58.5–76.8) with HBV-associated infection.

Age is another important prognosis factor. As previously detailed for cPAN, early-onset of the disease is associated with lower mortality, although higher relapse rates. This has been further confirmed in pediatric case-series [89, 96] and with direct comparison between adult- and childhood-onset PAN [97]. Of note, age is part of the prognostic FFS score detailed further.

Fulminating vasculitis, which may manifest gastrointestinal involvement, renal failure, pulmonary hemorrhage and rarely, cerebral involvement, may be unresponsive to treatment resulting in excessive mortality and morbidity in the first few months following diagnosis.

Relapse

In contrast to GPA and MPA, remission once obtained, disease tends to recur less frequently during first years in PAN. The outcome is even better during HBV-related PAN: in one large cohort [95] 8% of the HBV infection-associated PAN and 19% of the HBV-free PAN demonstrated a first relapse at 37 months and 29 months from disease onset respectively. In another cohort study, only 10% with HBV-related PAN relapsed [3]. Relapses associated with HBV infection occur in those with persistent active virus replication after treatment. A stepwise multivariate analysis [41] calculated hazard ratios (HR) and CI for independent predictors of relapse that included, HBV-related PAN (2.27 [95% CI 1.11–4.63]) and cutaneous manifestations at diagnosis (HR 1.85 [95% CI 1.08–3.23]), especially when only nodules were considered (HR 2.21 [95% CI 1.30–3.78]) Although the severity of relapses was unpredictable, rash and arthralgia conferred a more favorable prognosis for a

less severe disease status compared to the initial clinical presentation. Long-term follow-up studies until 8 to 10 years from disease onset indicated relapses rate of approximately 50% [98, 99].

* Including HBV-associated PAN. [†]Some patients may have died for example from heart disease due to vasculitis alone, treatments or other associated conditions, not always specified; hence, the total of listed causes exceeds 100%.

[‡]Includes cerebrovascular and cardiovascular complications. Abbreviations: ICU, intensive care unit; n, number.

Mortality

The major causes of mortality in PAN are shown in Table 5. Mortality can be divided into two types: those attributed to the vasculitic process involving major organ and others due to severe treatment-related side effects. While a few patients may die during the first few months of the disease due to unresponsiveness to treatment [73], the majority occur with

longer durations of multi-organ involvement associated with fever and rapid weight loss, especially those with gastrointestinal involvement. Mortality related to treatment side effects generally occur in the years following treatment for controlled or uncontrolled vasculitis with infections representing the primary cause of death due to intense initial therapy with corticosteroids and cytotoxic agents. Viral infections, notably *Pneumocystis jirovecii*, occur later in the course associated with profound drug-induced immunosuppression [100, 101]. A small number of patients suffer die within the first weeks or months following the diagnosis of PAN despite adequate treatment. Bourgarit and colleagues [73] showed that 38/309 (12%) patients died during the first year predominantly due to vasculitis (58%), while other deaths were related to treatment side effects or factors independent of vasculitis. The primary cause of early mortality in PAN is severe gastrointestinal involvement with associated perforation and hemorrhage, so noted by the FFS [65]; however, HBV infection was not a factor of severity. Among patients hospitalized in intensive care units (ICU), the main prognostic factor for early mortality was predicted by the Acute Physiology and Chronic Health Evaluation (APACHE) [102] which was not specifically devised for vasculitis. Neither the vasculitis-specific Birmingham Vasculitis Activity Score (BVAS) [103] nor the FFS scoring system [65], predicted ICU mortality [102].

TREATMENT

The FFS [105] is a useful guide to treatment, the associated features of which predicted increased mortality: proteinuria >1 g/day, renal insufficiency (serum creatinine >140 $\mu\text{mol/L}$ or 1.6 mg/dL), specific cardiomyopathy, gastrointestinal and CNS involvement. Although treatment should not be overly influenced by FFS criteria [105], they may be considered in deciding the therapeutic strategy. Accordingly, patients lacking the poorest prognostic symptoms (FFS = 0) may be treated with corticosteroids alone to reduce the number and severity of treatment related side effects. This strategy is effective with a few minor relapses necessitating transient dose intensification and addition of an immunosuppressant agent. The 1996 FFS for systemic necrotizing vasculitides was revisited [65]. The following factors were significantly associated with increased 5-year mortality: age >65 years, cardiac symptoms, GI involvement, and renal insufficiency (stabilized peak urinary creatinine ≥ 150 $\mu\text{mol/L}$ or 1.7 mg/dL) with each accorded +1 point; while ear, nose and throat manifestations were scored – 1 point, as they were associated with better outcomes. The 5-year mortality rates for FFS of zero, one, and ≥ 2 , were respectively 9%, 21% and 40%. The same strategy previously described for the 1996 FFS [105] has been applied to patients with PAN. Since then it has been shown that even if patients with FFS = 0 at diagnosis had good overall survival rate, relapses could occur up to 50%, particularly when mononeuropathy multiplex is present at diagnosis [106]. Moreover, these patients were frequently treated with immune-suppressant therapy as a consequence of GC resistance.

BVAS is another tool frequently used during SNVs to assess severity and prognosis. Comparisons between FFS and BVAS showed conflicting results regarding which one would be the best scoring system for PAN [73, 95, 107]. However, the two scores frequently parallel and FFS is very simple and readily usable in daily clinical practice.

Supportive care represents an important part of the therapeutic regimen for patients with potentially fatal disease. Pain control, prevention of pressure sores and physical therapy may be needed, especially for symptomatic mononeuritis multiplex. Angiotensin-converting-enzyme inhibitors are effective antihypertensive agents in those with renal vasculitis due to the beneficial effect on renal function. Persistent abdominal pain should lead to consideration of exploratory laparotomy to identify treatable bowel perforation; such patients may require medication via intravenous route to circumvent impairment of orally administered drugs. Rapid and severe weight loss due to severe gastrointestinal involvement can be counterbalanced with parenteral nutrition. Although weight loss is not a proven poor prognostic factor [65] common sense dictates the importance of optimizing all factors, notwithstanding optimal weight, that might mitigate increased susceptibility to infection rate with cytotoxic agents. Atherosclerosis is a potentially treatable comorbid factor that can worsen prognosis. The Vasculitis Damage Index (VDI) [108] is a useful measure of the cumulative impact of scars and sequela caused by the disease and its therapy. Since maximal immunosuppression is given at disease onset, antibiotic prophylaxis of opportunistic infections is often necessary but decided on an individual basis.

Immunosuppressant Medication

The introduction of corticosteroids, which led to an improvement in the untreated 5-year survival rate of 10% of the preceding two decades to 55% by mid-to-late 1970s [47, 48], further increased to 82% by the addition of cyclophosphamide and azathioprine [47, 109].

Corticosteroids

Corticosteroids are administered for only a few days in those with HBV infection, but is given as a prolonged course lasting up to one year in the presence of life-threatening organ involvement or the extension phase of mononeuritis multiplex, commencing with pulse methylprednisolone dose of 7.5 to 15 mg/kg IV over 60 min, repeated at 24-h intervals for 1–3 days. The side effects of an empiric dose of pulse-methylprednisolone dose <1000 mg are usually mild and transient in the short term. However, severe side effects which are fortunately rare include sudden death, cardiac arrhythmia, myocardial infarction, gastrointestinal bleeding, and seizures. This is followed by prednisone in doses of 1 mg/kg/day or the equivalent dose of methylprednisolone for two to three weeks after which tapering can begin. The FVSG trial [110] which tapered the corticosteroid dose by one-half to 20 to 30 mg per day by three months, aimed for a dose of 10 mg by six months, and 5 mg by one year. This gradual reduction had the advantage of limiting side effects. The results of a prospective trial devoted to treatment of vasculitides in the elderly ≥ 65 (CORTAGE) noted that the dose of corticosteroids could be even lower and still retain disease-free survival benefits [111].

Cyclophosphamide

Cyclophosphamide can be administered in combination with corticosteroids at a dose of up to 2 mg/kg/day oral route for three to six months. However, it is associated with major side effects including, hemorrhagic cystitis, bladder fibrosis, bone-marrow suppression, ovarian failure, bladder cancer, and hematological malignancy [112]. In addition, life-threatening infection can supervene when given in conjunction with high dose corticosteroids [73, 95]. Protocols employing intermittent treatment with higher dose of cyclophosphamide to limit the associated morbidity of daily doses were developed for the treatment of PAN [113]. Intravenous pulse cyclophosphamide is preferable to oral cyclophosphamide in the treatment of systemic necrotizing vasculitis. The FVSG protocol employs a dose of 0.6 g/m² given every two weeks for three pulses, followed by a schedule of every three weeks for a total of six treatments. The analysis of 2 cyclophosphamide regimen strategies, 6 vs 12 months treatment, during PAN and GPA was performed after a 10-year follow-up period of the CHUSPAN trial [99]. None of the strategies was superior, indicating 6 months may be a sufficient duration for cyclophosphamide. After initial cyclophosphamide regimen, a maintenance therapy with azathioprine or methotrexate, as recommended in the treatment of AAV [114, 115], is an acceptable yet invalidated approach in PAN. For patients over 65 years, the CORTAGE study indicated that low-dose of cyclophosphamide, i.e., maximum of 6 pulses of 500 mg each, was similar to classical FSVG protocol in terms of remission, but with a lower rate of severe adverse events [111].

For pediatric PAN, treatment is currently based on adult recommendations as no controlled trial has been performed specifically in this population. The MYPAN study in childhood PAN aims at comparing cyclophosphamide and mycophenolate mofetil as experts in the field judge this drug could be a good alternative [116].

It is the authors' opinion that cyclophosphamide should be given judiciously based upon the anatomical location and severity of PAN involvement, rather than to all PAN patients. Oral low-dose cyclophosphamide was successfully employed to control disease activity and relapses within the first six months of treatment in patients with systemic vasculitis who failed to respond to pulse intravenous high-dose regimen [117]. Patients with PAN and associated poor-prognostic factors should be treated with combination corticosteroids and cyclophosphamide for six months, followed by a corticosteroid agent and less toxic immunosuppressant such as azathioprine or methotrexate. Patients without such poor prognostic factors can be treated safely with corticosteroids alone and adjuvant immunosuppression introduced only in cases of treatment failure for disease control [118]. This is confirmed by the CHUSPAN2 randomized controlled trial that compared standard corticosteroid therapy to adjunction of azathioprine in SNVs and PAN without poor prognosis factors. After 12-months treatment period, the main end-points at 24 months were not significantly different between two groups for relapses rate, mortality, adverse events [119].

Other Cytotoxic Agents

Azathioprine, methotrexate and other cytotoxic agents are all reserved for patients with contraindications to the initial or continued use of cyclophosphamide, and as maintenance therapy for up to eighteen months.

Plasma Exchange

There is little support for the use of plasma exchange in PAN in the absence of HBV infection [120], including those with poor-prognosis factors [121]. Plasma exchange is a second-line treatment of PAN refractory to conventional therapy. Its use in patients with AAV is to limit renal disease sequela.

Rituximab

At present, and contrarily to AAV, there is no suitable pathogenic mechanism, published finding, or ongoing study of the use of rituximab in the treatment of PAN. The authors have used rituximab in rare patients with PAN following failure of other treatments.

HBV-Related PAN

Patients treated with conventional regimens of corticosteroids and cyclophosphamide allows HBV to replicate, facilitating the development of chronic hepatitis and liver cirrhosis. Therefore, a preferred initial treatment commences with plasma exchange combined with vidarabine or interferon- $\alpha 2b$, and corticosteroids. This controls the most common life-threatening manifestations of PAN during the first few weeks of disease. Afterward, corticosteroid agent is safely discontinued enhancing the immunological clearance of HBV-infected hepatocytes favoring anti-HBeAb seroconversion. This strategy [122, 123] which is preferred over conventional regimens, was confirmed among 41 patients, 23 (56.1%) of whom no longer exhibited serological evidence of replication, and an overall cure rate of 80.5% [124]. The antiviral agent lamivudine [3], which increases the seroconversion rate from 56.1% to 60%, did not confer additional improvement in the survival rate at 18 months. Those treated with conventional corticosteroids with or without cyclophosphamide and no antiviral drugs demonstrated a mortality rate of 27.5% at 18 months compared to 17.5% when combined antiviral therapy was offered ($P = 0.46$). The benefits of adjunctive antiviral therapy appear after prolonged follow-up, since these drugs lower the risk of cirrhosis or liver failure. In 2017, treatment protocol guidelines for classical HBV infection (without PAN) highlight the need for long-term administration of nucleoside analogues limiting viral resistance such as tenofovir or entecavir [125]. This strategy has not yet been proven useful in HBV-associated-PAN.

Localized PAN

Localized forms of PAN without poor-prognostic factors can be treated initially without immunosuppression, awaiting refractory or relapsing disease. Isolated appendix or gallbladder involvement is associated with a favorable prognosis after surgical removal [126]. Cutaneous PAN, particularly in childhood forms, can be successfully treated with colchicine or dapsone in combination with topical corticosteroids. Colchicine and dapsone are both effective against PAN restricted to skeletal muscles.

CONCLUSION

Polyarteritis nodosa is an exemplary multi-systemic medium-sized, primary systemic vasculitis of adults and children. Once the most frequent vasculitis, it has become progressively less common notably in developed countries due to eradication of hepatitis B virus infection. Effective treatment of polyarteritis nodosa which includes consideration of corticosteroids and cyclophosphamide depending upon the presence of favorable or unfavorable prognostic factors, and an antiviral regimen when complicated by hepatitis B infection, has improved the 5-year survival of patients.

ABSTRACT

Giant cell arteritis (GCA) or large-vessel GCA (LV-GCA) is a chronic, idiopathic, granulomatous vasculitis of medium and large arteries comprising overlapping phenotypes of cranial arteritis and extra-cranial GCA. Vascular complications associated are generally due delay in diagnosis and initiation of effective treatment. Advancements in magnetic resonance imaging (MRI) and MR angiography (MRA), computed tomography angiography (CTA), ¹⁸fluoro-deoxyglucose/positron emission tomography (FDG/PET) and color duplex ultrasonography, have led to improved diagnosis of GCA. Corticosteroids are the mainstay of therapy in GCA. However, their use is associated with predictable and occasionally serious side effects. Biological agents including tocilizumab are effective and safe corticosteroid-sparing agents in treating GCA.

Keywords: giant cell arteritis, vasculitis, temporal artery biopsy, temporal artery ultrasound

INTRODUCTION

In the 10th century, Ali ibn Isâ described a man with heat and inflammation of the temporalis muscle and loss of sight [1]. In 1890, Hutchinson [2] described painful inflamed temporal arteries that prevented a man from wearing his hat. Giant cell arteritis (GCA) also known as large vessel (LV)-GCA, which was characterized as a distinct entity by Horton in

1932 [3], is now recognized as the most common primary systemic vasculitis of the Western world in those aged over 50. The 2012 Revised Chapel Hill Consensus Conference (CHCC) Nomenclature [4] categorizes GCA as a large vessel vasculitis (LVV) prompting use of the equivalent term, large vessel (LV)-GCA. The spectrum of morphological changes have been described [5, 6]. This chapter reviews the epidemiologic, clinicopathologic features, diagnosis and treatment of giant cell arteritis.

OVERVIEW

The clinical symptoms in GCA are usually due to inflammation of the medium sized extra-cranial branches of the carotid artery, particularly the superficial temporal division [7]. About one-half the time, GCA is accompanied by aching and stiffness of the shoulder and hip girdles typical of polymyalgia rheumatica (PMR). Unfortunately neither the classical clinical presentation nor the combinations of clinical symptoms and signs predictive of a definite diagnosis of GCA occur commonly [8]. Visual loss in one or both eyes can be averted by early diagnosis and prompt treatment [9]. Temporal artery biopsy (TAB) is the gold standard of diagnosis, perhaps guided by non-invasive temporal artery ultrasound (TAUS). Glucocorticoids or corticosteroids (CS) remain the best treatment for GCA with similar long-term survival rates as age-matched population controls [10]. There are no randomized clinical trial (RCT) data in GCA to decide the correct CS dose regimen. Recent international guidelines [11, 12] provide assistance in diagnosis and treatment although the evidence base is weak and the guidance is at best advisory. The introduction of GCA care pathways may improve patient outcome [13, 14].

EPIDEMIOLOGY

The lifetime risk of developing GCA is estimated at 1% for women and 0.5% for men [15]. The disease rarely occurs in individuals under the age of 50 years and peaks in the eighth decade of life. It more commonly affects Scandinavians and North Americans of Scandinavian descent than Southern Europeans [16], and occurs rarely in Black and Asian populations [17-20]. Such racial patterns together with familial aggregation [21] point to a genetic predisposition to the disease. There is an association with the *HLA-DRB1*04* allele [7, 22].

The geographical variation and seasonal fluctuation of GCA in turn suggests a contribution from environmental and infectious factors [23] although definite links to particular microorganisms or vaccinations [24-26] have not been established. Moreover, there is no evidence that GCA occurs with increased prevalence in association with malignancy or as a paraneoplastic syndrome [27]. GCA is likely a polygenic disease wherein multiple environmental and genetic factors influence susceptibility and severity [28].

PATHOLOGY

The classical histological changes of GCA include arterial wall inflammation, internal elastic lamina fragmentation and intimal thickening (Figure 1). Although GCA derives its name from the presence of multinucleated giant cells, the latter are seen in only about one-half of positive TAB, albeit in association with a granulomatous inflammatory infiltrate composed of CD4⁺ T-cells and macrophages located at the intima-media junction near fragments of the internal elastic lamina. Other TAB specimens manifest lymphomononuclear-predominant panarteritis with occasional neutrophils and eosinophils without giant cells [29].

Figure 1. Temporal artery biopsies. (A) Normal (B) Typical GSA showing inflammation of the arterial wall, fragmentation of the internal elastic lamina, intimal thickening and luminal occlusion.

In a small minority of TAB, inflammation may only be seen in peri-adventitial vessels external to the adventitia or the vasa vasorum in a network of small blood vessels that supply larger ones [30]. There is considerable variation in histopathology between patients as well as within a given TAB tissue sample [29]. Arteritic involvement of a given artery may be focal and segmental leading to skip lesions [7]. There may be healed arteritis suggested by intimal thickening, fragmented elastic lamina and scarred media, although these may in part be age related changes [31]. Arterial wall thickening can lead to partial or complete occlusion of the lumen and ischemic complications such as anterior ischemic optic neuropathy (AION) [23]. One subset of patients has small-vessel vasculitis surrounding non-inflamed temporal artery segments in TAB tissue specimens [30, 32], but there is no indication that such patients should be considered any differently than typical GCA. Arteritis of the temporal artery is not entirely specific for GCA, and can be encountered with polyarteritis nodosa (PAN), anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), malignancy, and atypical PMR [33-37].

IMMUNOPATHOGENESIS

Inappropriate activation, maturation and retention of antigen presenting adventitial dendritic cells are early steps in the pathogenesis of GCA [24, 38]. These cells sample the

surrounding environment for viral and bacterial pathogens through the action of toll-like receptors (TLR) wherein particular TLR profiles appear to be vessel specific [39] which may explain why some blood vessels are more prone to be targeted by GCA than others. Mouse models [40] show that activated vessel wall-embedded dendritic cells release chemokines that recruit CD4⁺ T-cells and macrophages. Moreover the pattern of arterial inflammation corresponds to TLR specificity such that TLR4 stimulation induces panarteritis and TLR5 stimulates perivasculitis [41].

At least six observations support a T-cell mediated etiopathogenesis of GCA according to Borchers and colleagues [23]. First, the inflammatory cell infiltrate in GCA is comprised mainly of T-cells and macrophages with few or no B-cells and polymorphonuclear cells notably neutrophils are often absent. Second, the formation of granulomas depends upon T-cells, particularly the CD4⁺ subset. Third, infiltrating T-cells in GCA lesions demonstrate main histocompatibility class II and IL-2 receptor expression with selective T-cell clonal expansion in TAB tissue specimens. Fourth, GCA is associated with specific human leukocyte antigen (HLA) alleles. Fifth, there is attenuation of vascular inflammation after depletion of T-cells in experimental models of GCA. Lastly, two types of T-cells that play important roles in GCA, Th1 and Th17, express high levels of interferon (IFN)- γ mRNA compared in TAB specimens compared to control samples without arteritis [23]. The balance between Th1 and Th17 may contribute to the clinical presentation of GCA since T-cell derived IFN γ correlates with visual symptoms and jaw claudication in a manner that those with high levels demonstrate more intense intimal hyperplasia in tissue samples [42]. In addition, T-cell derived IFN γ expression may contribute to CS resistance leading to a more chronic course, as well as the heightened expression of giant cells, ischemic complications, and neo-angiogenesis [23] and constitutional symptoms of GCA [38, 43]. The pro-inflammatory cytokine interleukin (IL)-6 appears to be a good target molecule to induce remission in GCA as serum levels mirror disease activity and IL-6 is up-regulated in the inflamed vessels of patients with GCA [44]. Macrophages are thought to be the effector cells in GCA as they are the major source of many cytokines and other drivers of the inflammatory process such as IL-1 β , IL-6, TNF, TGF β , IL-32, matrix metallo-proteins and platelet derived growth factors that are over expressed in TAB, however their precise role remains to be elucidated [23]. IL-6 concentrations correlate with a strong inflammatory response in GCA but appear to be inversely related to GCA related ischemic events. IL-6 is also a potent inducer of angiogenesis leading to the hypothesis that collateral vessel formation in the presence of high levels of IL-6 may be protective [45].

CLINICAL FEATURES

The onset of GCA tends to be insidious over weeks to months, and abrupt in up to 20% of patients [28], with a spectrum of initial disease manifestations attributable to the localized effects of vascular and systemic inflammation [46, 47] including new-onset headache, scalp tenderness, jaw claudication, fever, fatigue, malaise, anorexia, weight loss polymyalgia, and visual loss [48]. The artificial separation of cranial and extracranial features either localized to the head or owing respectively to large vessel involvement is misleading as postmortem studies show that the intracranial arteries are largely spared in GCA [49].

Headache

Although headache is a prominent feature, it is not universal [46, 50-52]. Classically it tends to be a constant ache of sudden onset in the temporal region and is usually severe enough to disturb sleep [51, 53]. It can vary greatly in intensity and location, be constant or intermittent, and assume virtually any form mimicking tension-type headache, thunderclap, migraine and even cluster headaches [1]. It may become progressively worse, or wax and wane, temporarily subsiding in the absence of treatment [54]. A key feature is that it typically differs from any other previously experienced headache, and for this reason, the patient may deny headache, instead calling the symptom head pain [55]. The headache may be associated with scalp tenderness especially on hair brushing and combing or wearing glasses [47]. When severe, even the slightest pressure on resting the head on a pillow may be intolerable. Pain is usually localized to one or both temporal regions, the forehead or occiput. However, the pain may be generalized, spare the scalp altogether or affect the eye, ear; face, jaw or neck [55]. Tenderness, prominence and decreased temporal artery pulsation (Figure 2) increase the likelihood of GCA [46], although one-third of TAB-proven GCA patients have normal temporal arteries on clinical examination.

Figure 2. Prominence of the temporal artery in GCA.

Jaw Claudication

Although the most specific feature of GCA, jaw claudication, or pain and fatigue in the masseter muscles on protracted or vigorous chewing that eases with rest, is present only in about one-half of patients, it can also have an abrupt trismus-like symptom [54] and remain intermittent for weeks or months [55]. Jaw claudication should not be confused with temporomandibular joint (TMJ), tooth or gum disease. Tongue claudication is less common.

Constitutional Findings

With the widespread availability of CS in the empiric treatment of GCA, constitutional symptoms such as fever, fatigue, malaise, anorexia and weight loss are less often encountered at the formal diagnosis of affected patients [55]. Fever which occurs in about one-half of patients is usually low grade. A small number of TAB-proven patients with GCA present with only symptoms of systemic inflammation without localizing vascular symptoms [29, 51, 56].

Ophthalmologic Involvement

An estimated 15% of patients with GCA experience ophthalmologic complications [57], notably ischemic optic neuropathy (AION) due to arteritic involvement of the short posterior ciliary arteries supplying the optic nerve head [58, 59], with the remainder comprised mainly of retinal blindness due to central retinal artery involvement [58, 59]. Visual loss is painless, partial or complete, and unilateral or bilateral; and once established it is usually irreversible [38]. It may be preceded by fleeting visual blurring with exercise, amaurosis fugax or diplopia, but commonly occurs without warning and may be the presenting symptom [46, 60]. Ophthalmoplegia is usually due to a partial or complete oculomotor or abducens nerve palsy, and is a recognized complication of ischemia affecting the extra-ocular muscles, cranial nerves or brainstem [14].

Other ischemic complications of GCA include transient ischemic attack (TIA) and stroke which may occur due to thrombosis, microembolism or a combination of intimal hyperplasia and distal thrombosis [55]. Although the vertebral arteries are inflamed in the large majority of patients at postmortem examination [49], clinically significant vertebrobasilar insufficiency is uncommon [55]; scalp and tongue necrosis are rare [61].

Polymyalgia Rheumatica

Although up to one-half of patients with GCA develop inflammatory shoulder and hip girdle pain and stiffness [62], only about 5% of patients with frank PMR ever develop GCA [7].

Large Vessel Involvement

Aortic inflammation can be observed in surgical biopsies or at postmortem examination in GCA [5, 63] however the true frequency is difficult to ascertain. Computed tomography angiography (CTA) [6] and helical aortic computed tomodensitometry [64] discern aortic involvement in 45 to 65% of patients with GCA, with the thoracic aorta most often affected. The relationship between aortitis and subsequent aortic aneurysm remains unclear [65]. In the first year of the disease, aortitis confers a small significant risk of dissection or rupture even in the absence of aortic aneurysm with resultant high mortality. Long term dilatation or aneurysm formation can occur with an increased risk of rupture [66, 67]. Retrospective

studies note aortic aneurysm and dissection in 3% to 18% of patients with GCA [66-70]. In a cross-sectional study employing CT, 12/54 (22.2%) patients with GCA developed aortic aneurysms after 4 to 10.5 years [63] with relative risks (RR) ranging from 3 to 17.3 [66, 71]. Distal stenotic lesions of the subclavian, axillary and brachial arteries occur in 3% to 15% of patients [51, 67, 72, 73]. Lower extremity arteries are infrequently affected [67], however the identification of claudication and vascular bruits is important to ascertain before initiation of empiric CS because such findings, which add weight to the formal diagnosis of GCA, may resolve with effective treatment [70, 74]. The management of peripheral arterial involvement rarely requires surgical intervention [55, 70, 75].

DIAGNOSIS

Classification Criteria

The American College of Rheumatology (ACR) 1990 criteria for the classification of GCA [76] required the presence of three or more of the following including, age >50 years, new onset localized headache, temporal artery tenderness or decreased pulsation, erythrocyte sedimentation rate (ESR) >50 mm/hr, and abnormal TAB, yielding a sensitivity of 93.5% and specificity of 91.2% to discern GCA from other vasculitides.

Table 1. Positive predictive value of clinical features of GCA*

Clinical Features Associated With a positive TAB	PPV Positive Predictive Value	Percentage of Patients
New headache	46%	49%
Scalp tenderness	61%	18%
Jaw claudication	78%	17%
Double vision	65%	10%
Jaw claudication + Scalp tenderness + New headache	90%	6%
Jaw claudication + Double vision or decreased vision	100%	0.7%

*Adapted from [8]. Abbreviations: GCA, giant cell arteritis; PPV, positive predictive value; TAB, temporal artery biopsy.

In the absence of consensus with regard to diagnostic criteria for GCA, the ACR criteria [76], jaw claudication, diplopia, temporal artery beading, prominence and tenderness increased the likelihood of positive TAB [46]. Jaw claudication in association with diplopia or decreased vision, or scalp tenderness and new headache were likewise predictive of GCA (Table 1). The insensitivity of the ACR Classification criteria is exemplified by the potential enigma of an 85-year-old man with headache, jaw claudication, loss of vision, temporal artery pain, and a clinically abnormal temporal artery who might only have a pre-TAB probability of GCA of 68% [77] emphasizing the difficulty in ascertaining a conclusive histopathologic diagnosis even when the clinical features are highly suggestive.

Laboratory Studies

Blood Studies

Acute phase markers of inflammation are often significantly elevated, and a normocytic normochromic anemia and thrombocytosis may be present [78], as may elevation of liver transaminase levels [79], while the serum albumin level may be depressed. The presence of rheumatoid factor, antinuclear (ANA) and other autoantibodies are not present in greater frequency than in the general population; however ascertainment of serum ANCA may help to differentiate GCA from other forms of vasculitis. Although the ESR has historically been the acute phase measure of choice in the diagnosis of GCA, up to a quarter of patients may have a normal value [47, 80-82] and elevation of the C-reactive protein (CRP) is a better predictor of obtaining a diagnostic TAB [9, 81, 83, 84]; the combination of an elevated CRP and positive TAB render the highest sensitivity and specificity for the diagnosis of GCA. Only 1 in 119 (.8%) patients to 7 in 177 (4%) patients [81, 84] with GCA presented with both normal ESR and CRP levels, however such findings may be subject to selection and referral bias. We routinely measure the CRP and plasma viscosity in all patients with suspected GCA since the latter has the advantage of paralleling the ESR, uninfluenced by age, gender, hematocrit or time to analysis.

Temporal Artery Biopsy

Temporal artery biopsy has been the gold standard test representing definitive pathological diagnosis [7, 13, 14, 38, 46, 55]. Performed correctly, TAB carries a low procedural risk of significant complications [77], and a positive result removes later doubts about diagnosis, particularly if treatment causes complications [85, 86] or if the patient fails to respond promptly to therapy [87], whereas a negative biopsy is important in averting long term risk of empiric CS [88]. Up to one-third of clinicians surveyed did not recommend TAB for the diagnosis of GCA [89] possibly because it did not alter the perceived necessity of empiric therapy when the result was inconclusive or negative [90-92]. The true sensitivity of unilateral TAB was 87% employing Bayesian analysis [93] with a variation in sensitivity of 24% to 94% in clinical cohorts [87]. The likelihood of a false-negative TAB may be influenced by the length of the specimen, the duration of prior CS therapy, pathological sectioning techniques and the presence of predominantly non-cranial disease. Retrospective reviews suggest a post-fixation biopsy length of 1 to 2 centimeters (cm) is adequate [94-97], but a length of greater than 2 cm was also recommended [97- 100]. A length of artery nearer to 3 cm probably allows for post fixation shrinkage [99]. Whether bilateral biopsies should be performed depends on the rate of discordance, which in a pooled analysis of four studies looking at 439 synchronous bilateral biopsies was 5.9% [93], although the range in individual studies was 1.4% to 12.7% (101). If the selected artery is negative for arteritis, some investigators [29, 88] advocate biopsy of the temporal artery on the contralateral side while others [12] consider the additional burden on the patient not justified for the small increase in diagnostic yield particularly if an adequate length of unilateral specimen can be ascertained and reviewed by an experienced pathologist in TAB analysis [55, 99]. The side selected for TAB should be the one, if present, with lateralizing symptoms or signs [102].

Temporal Artery Ultrasound

Temporal artery ultrasound studies (TAUS), which are cost-effective, non-invasive and lack significant complications, take about five minutes to perform, and render an image of the inflamed temporal artery characterized by edematous wall swelling. The latter conforms to a dark hypoechoic circumferential halo sign that represents continuous or segmental wall thickening (Figure 3).

Figure 3. Temporal artery ultrasound (TAUS). The hypoechoic “halo” sign (asterisks) on (A) longitudinal and (B) transverse section. (C) and (D) normal artery.

References: Study a (174); Study b (104); Study c (116). Abbreviations: TAUS, temporal artery ultrasound.

Figure 4. Proportion of positive temporal artery ultrasounds as a function of days on treatment with corticosteroids. An estimate of the mean length of treatment at two time points was made from each study listed below and plotted on the chart. The thickness of the lines represents the number of subjects reported in the study. Study c allowed two such estimates.

Stenosis and occlusion common in elderly patients due to atherosclerosis, neither of which are specific or sensitive for GCA, may also be noted [103, 104]. Three meta-analyses [105-107], which demonstrated the usefulness of the halo sign in the diagnosis of GCA with a sensitivity of 68% and specificity of 91% for a unilateral halo sign, showed 100% specificity for the bilateral halo sign. However, the findings may be influenced by CS use; moreover there is a presumed limited window of opportunity wherein which to correctly ascertain the diagnosis [65]. One-half of positive TAUS findings may be missed within seven days of treatment initiation (Figure 4), implying that in order to avert the low sensitivity of TAUS in those with suspected GCA, the study should be performed as soon as possible, preferably before or on the first day of treatment. Some [108] argue that it is never too late to perform TAUS because even if the sensitivity is diminished, the specificity remains. Therefore there is a rationale for its use as it has the potential to avert the need for TAB when a halo sign is noted. Furthermore, it can increase the diagnostic yield of TAB by directing the incision site to the most affected area of artery [104, 109].

Other Imaging Studies

Whereas non-invasive vascular imaging may be useful when there is atypical extracranial large vessel involvement or limb claudication and persistent acute phase reactants or fever of unknown origin [110], conventional angiography has little if any role unless a surgical intervention is contemplated [111]. Ultrasound of the thoracic aorta is generally inadequate but it may provide useful information in proximal upper limb arteries to increase the diagnostic yield of GCA [112]. Both magnetic resonance imaging (MRI), MR angiography (MRA), and contrast-enhanced computerized tomographic angiography (CTA) provide useful images of mural and luminal changes suggestive of large vessel vasculitis in GCA [6, 64, 113, 114] that include circumferential wall swelling, smoothly tapered luminal narrowing of aortic branches and aortic aneurysm formation [111]. Moreover, MRI and MRA which do not lead to radiation exposure are favored over CTA by some specialists [38, 101].

Bright mural enhancement of the temporal artery on contrast-enhanced high-resolution MRI had comparable sensitivity and specificity to TAUS in the diagnosis of GCA in one retrospective single-center analysis [115], the latter of which decreased in sensitivity over the first few days of CS treatment (85% after 0-1 days, 64% after 2-4 days, 56% after >4 days) [116].

Whole body ¹⁸Fluorodeoxyglucose (FDG)-positron emission tomography (PET) increased the overall diagnostic accuracy of large vessel involvement in GCA from 54% to 70% [117]. One meta-analysis [118] found that the absence of FDG uptake conferred a negative predictive value of 88% of GCA, whereas thoracic vascular uptake was highly suggestive of GCA. However there have not been properly designed trials to assess the sensitivity and specificity of ¹⁸F-FDG PET in GCA, nor does it reliably distinguish between atherosclerosis and vasculitis [119]. The radiographic features of large-vessel involvement so noted in CTA and PET imaging decrease rapidly after the initiation of CS treatment; features of large-vessel vasculitis including concentric wall thickening were significantly more frequent in treatment naïve patients compared to patients treated with corticosteroids for 1-3 days (77% versus 29%, $p = 0.005$) [6]. The diagnostic accuracy of PET in detecting large-vessel involvement was significantly higher in patients not receiving immunosuppressive therapy (93.3% vs 64.5%) [117].

Rapid Diagnostic Pathway

The authors advocate a clinical review of patients within 24 hours of suspected GCA, including access to specialty assessment for the performance of necessary blood tests, followed by TAUS, and TAB within seven days [13, 14, 55]. The threshold is kept low for the performance of TAUS or TAB in all patients suspected of GCA awaiting the findings before commencement of CS in the absence of visual disturbances and jaw claudication [8]. The risk of blindness in other patients with typical GCA while awaiting results of laboratory studies is carefully weighed against the risk of potentially serious medication side effects associated with empiric CS treatment. The cost effectiveness of such pathways in secondary care has yet to be calculated, but visual loss particularly in the elderly, has major consequences for quality of life [14]. While those with monocular vision loss would trade one in three of their remaining years for unimpaired vision, this rose to two in three in those with binocular vision [120].

PROGNOSIS

Clinical studies have not validated the relation of existent classification criteria for GCA [76] to clinical and laboratory measures to prognosticate relapse likelihood and outcome. Common features of clinical relapse include recurrent headache, scalp pain and PMR-like symptoms associated with a raised acute phase response reactants [121-124]. Clinical symptoms and changes in the acute phase response can occur independently [125]. Acute phase responses can take several weeks to return to normal after initiating treatment while symptoms improve over several days [126, 127]. It can be argued that maintaining the lowest level of acute phase response achieved for each individual patient is an important goal of therapy [128] but pursuing a normal acute phase response might lead to overtreatment and unacceptably high rates of CS-related adverse events. Up to 20% of patients with a significant asymptomatic rise in ESR failed to relapse clinically [122] although clinicians may be overly concerned that improved control of the acute phase response may be protective against late atherosclerosis [129]. It seems reasonable to consider a return to higher dose treatment to improve prognosis in patients experiencing a returning headache, PMR-like symptoms, jaw claudication and visual symptoms. Since the advent of CS for GCA, the long term outcome and survival rates have been similar to age matched population [27, 130] including those with large vessel complications [131], although prior to CS estimated mortality was 12.5% [132]. The presence of clinical or subclinical aortitis could infer a poorer prognosis [6, 68] but this requires further corroboration. It is uncertain to what degree aortic involvement so noted on imaging studies resolves with standard GCA therapy, or whether it predicts a more chronic and relapsing GCA course requiring continued or more aggressive treatment [64, 68, 133]. Standard chest radiography, echocardiogram, CT, MRI and PET imaging have all been used to screen for emerging thoracic aortic dilatation [12, 38, 63, 67, 131, 134]. However there are no prospective studies comparing the sensitivity of these studies separately or together in discerning thoracic aortic aneurysm formation. Mackie and Pease [55] advocate tight control of blood pressure without regular imaging.

TREATMENT AND OUTCOME

Most experts including the British Society of Rheumatology (BSR) and European League Against Rheumatism (EULAR) recommend early initiation of high-dose CS therapy before TAB, although the evidence for this approach is weak with a level of evidence equal to 3 and strength of recommendation equal to C [11, 12]. The case can be made for early intervention with empiric treatment in patients with visual loss since untreated, the other eye is at heightened similar risk in up to one-third of cases for the ensuing three weeks [121], moreover partial visual improvement in vision is more likely if treatment commences within the first day of visual loss [135]. A similar approach may be advocated in those with features of impending visual loss such as amaurosis fugax, diplopia and jaw claudication. However, if the likelihood of GCA is low to moderate, withholding treatment and awaiting TAB that later returns negative would avoid unnecessary treatment. Figure 5, which show the proportion of positive TAB biopsies in relation to the number of weeks taking corticosteroids among several reported cohorts [8, 87, 136-138], suggests a 5% to 10% loss of TAB positivity for each week of treatment. While those with initially high likelihood of GCA pretreatment will have persistently high rates of TAB positivity weeks later, the latter would not likely influence therapeutic decisions unless such patients suffer later relapse or manifest treatment related side effects that questioned need for continued therapy. A bilateral TAB length of > 3cm so noted in one-half of specimens, predicted the subsequent need for corticosteroid therapy in 94% of patients [139], whereas a negative TAB measuring >2 cm performed before six days of starting prednisolone led to cessation of therapy without later visual loss [140].

Figure 5. Proportion of positive TAB biopsy specimens as a function of weeks on treatment with glucocorticoids. An estimate of the mean length of treatment at two time points was made from each study report listed below and plotted on the chart wherein the thickness of the lines represented the number of subjects reported in the study. References: Study a: (136); Study b: (137); Study c: (87); Study d: (138); Study e: (8). Abbreviation: TAB, temporal artery biopsy.

Although there are no RCT of the use of CS in GCA [11, 12], most experts agree with daily morning treatment of prednisone at doses of 40 mg to 60 mg until symptoms and laboratory abnormalities resolve [7, 11, 12, 122]. Alternate daily CS were not as effective as a daily regimen, alone or in association with adjuvant methotrexate for GCA [122, 141]. In fact, the symptomatic response that follows CS treatment is so striking and rapid in GCA, that it is a diagnostic criterion of the disease [122]. Patients with PMR experience improvement in symptoms related to systemic inflammation over two to three days while symptoms related to impaired blood flow such as jaw claudication and visual disturbance generally take longer to respond and resolve [142]. Although sustained visual loss may be permanent and unresponsive to therapy [143], the risk of further progression is low [144]. Although prednisone in the dose range of 10 mg to 40 mg per day was effective in several cohorts [90, 145, 146], the results were not considered conclusive due to small sample sizes and apparent selection bias [86, 147]. Pulsed intravenous methylprednisolone was advocated in patients with GCA and visual disturbances [11, 12], however one observational study [128] and another RCT [148] failed to demonstrate improved efficacy in preventing visual loss compared to high-dose oral therapy. Moreover, intravenous pulsed methylprednisolone, which demonstrated no significant long term CS-sparing effects in the treatment of simple forms of GCA, was reserved for complicated forms of GCA.

The concern for CS resistance in patients with GCA has its origin in the ophthalmology community where visual loss in GCA is more prevalent [128]. One small RCT [149] that administered three consecutive days of one gram of intravenous pulsed methylprednisolone induction, followed by oral CS found higher rates of remission, less relapses, and more rapid tapering compared to patients treated with oral high-dose CS.

The apparent corticosteroid-sparing benefit of pulsed intravenous methylprednisolone [149] may not have been clinically significant since the criteria for disease relapses included instances of raised acute phase responses without clinical flares; moreover there were no differences in CS-related side effects [129]. The CS dose can be gradually tapered in the first month after the resolution of reversible clinical symptoms and the levels of acute phase reactants falls by 50% [11, 12]. Although other tapering regimens have been employed [122, 142], the available evidence [90, 142, 146, 150, 151] suggests that treatment should be continued for at least two years, with most patients weaned off of medication by four to five years. A minority of them may need continued low-dose CS [85, 121]. Among several GCA treatment trials conducted between 1988 and 2003 [90, 121-123, 142, 145, 146], the median duration of treatment of GCA ranged from 24 to 191 weeks, with an equivalent cumulative dose of prednisone that ranged from 5,275 mg to 9,194 mg. Such broad differences in the duration and dosage of administered CS would be expected to translate into a spectrum of relapse rates so noted in 27% to 84.2% of patients, with increased rates among those receiving the highest initial CS doses with more rapid tapering.

A meta-analysis of the use of adjuvant treatment with methotrexate [152] calculated the time-to-event outcomes in three randomized, placebo-controlled trials of patients with newly diagnosed GCA treated with initial high-dose CS and randomly assigned to 7.5 mg to 15 mg per week of oral methotrexate therapy or placebo [122, 123, 153]. There was a reduction in the cumulative equivalent dose of prednisone by 842 mg in 48 weeks ($P < 0.001$), but prednisone only treatment was reduced rapidly, and the rate of relapse in this group was 80% and it did not reflect current treatment practice. Current guidelines [12] of a recommended CS tapering regimen were loosely based on clinical experience at the Mayo Clinic [142] with the

consensus of a group of international clinicians. Some clinicians prefer slower dose reduction regimens with a lower anticipated rate of relapse [13], while others [126, 128, 154] favor individualized dose reduction schedules based on regular clinical review. The main drive to keep the CS dose to a minimum is the fear of adverse CS effects, particularly cardiovascular and bone fractures. Several cohort studies [90, 142, 146, 155, 156] suggested the clear association between the cumulative dose of steroids and the rate of CS complications other than cardiovascular and bone fracture, whereas others [67, 68, 71] were variably confounded by patients with differing severe disease requiring more aggressive treatment. The meta-analysis by Mahr and colleagues [152] noted adverse events in two-thirds of patients treated with CS alone, with methotrexate or placebo that included infection, abnormal liver function tests, fractures, diabetes, malignancy, thrombocytopenia, and leukopenia in descending order of frequency.

There is evidence from single case reports and small patient series of a clinical benefit in GCA employing the pyrimidine inhibitor leflunomide [157], and the immunosuppressants mycophenolate mofetil [158] and cyclophosphamide [159], however their efficacy has not yet been confirmed in RCT. Cyclosporin showed no additional CS-sparing effect in GCA [160].
